# M269 Algorithms, Data Structures and Computability

- Presentation 2018 | Exam
- ▶ Date Friday, 14 June 2019 Time 14:30–17:30
- There are TWO parts to this examination. You should attempt all questions in **both** parts
- ▶ Part 1 carries 65 marks 80 minutes
- ▶ Part 2 carries 35 marks 90 minutes
- ▶ **Note** see the original exam paper for exact wording and formatting — these slides and notes may change some wording and formatting
- ▶ Note The 2015J exam and before had Part 1 with 60 marks (100 minutes), Part 2 with 40 marks (70 minutes)

- Answer every question in this part.
- ► The marks for each question are given below the question number.
- Answers to questions in this Part should be written on this paper in the spaces provided, or in the case of multiple-choice questions you should tick the appropriate box(es).
- ► If you tick more boxes than indicated for a multiple choice question, you will receive no marks for your answer to that question.
- ▶ Use the provided answer books for any rough working.

A. A specification of an algorithm in structured English is a formal description of the inputs and outputs for that algorithm.

- B. A problem is computable if it can be expressed as an algorithm.
- C. An algorithm will always terminate.
- D. A problem for which the result is yes or no, is a decision problem.

Part 2 Q 16 Q 17

### Q 3 (6 marks)

- ➤ You are given two data structures. The first is an unordered list of integer values without duplicates, the second is an ordered list of integer values without duplicates.
- ► Here are examples of such lists, you will not need to use these lists to answer the question:

Unordered List: [ 17, 99, 25, 31, 39, 77, 83, 89, 41, 52, 67, 69, 2, 16, 91 ]
Ordered List: [ 2, 16, 17, 25, 31, 39, 41, 52, 67, 69, 77, 83, 89, 91, 99 ]

- For a list with n items
- (a) What are the best-case and worst-case Big-O complexities of a linear search over an un-ordered list?
- (b) What are the best-case and worst-case Big-O complexities of a binary search over an ordered list?
  - Q 3 continued on next slide

#### Q 6 (contd)

From the options below, select the two that represent the correct combination of T(n) and Big-O complexity for this function.

You may assume that a step (i.e. the basic unit of computation) is the assignment statement.

(Tick **one** box for T(n) and **one** box for Big-O complexity.)

A. 
$$T(n) = 3n^3 + 2n^2 + n + 4$$
 I.  $O(n)$ 

B. 
$$T(n) = 3n^3 + 2n^2 + n + 3$$
 II.  $O(n^2)$ 

C. 
$$T(n) = 3n^2 + 2n + 3$$
 III.  $O(3n^2)$ 

D. 
$$T(n) = 3n^2 + 2n + 3$$
 IV.  $O(n^3)$ 

E. 
$$T(n) = n + 10$$
 V.  $O(3n^3)$ 

 $\triangleright$  Explain how you arrived at T(n) and the associated Big-O complexity.

- A. Hash tables don't always require key values to be unique.
- B. Linear probing always examines every storage location in a hash table.
- C. The load factor is a measure of how many collisions have occurred when using a hash table.
- D. A collision occurs when two key values map to the same location in a hash table.

Q 13

Q 14

Q 15 Part 2

Q 16

Q 17

Prentn 2018 I Exam Solns

(c) Explain your answer to (b) [in the box below].

You need to consider any relevant values for the variables, and show, using the domain and interpretation on the previous page, whether they make the formula TRUE or FALSE.

In your explanation, make sure that you use formal notation.

For example, instead of stating Serenity hasn't docked at Poole you would need to write (Serenity, Poole)  $\notin \mathcal{I}(has\_docked\_at)$ 

(d) Give an appropriate English translation of the well-formed formula:

 $\forall X.(\neg \mathsf{has}\ \mathsf{docked}\ \mathsf{at}(X, poole) \to \mathsf{homeport}(X, \mathsf{dover}))$ 

Q 13 (4 marks)

► The interpretation of the previous question can also be represented by a database containing the following tables and data:

### homeport

boatname	home
Serenity	Plymouth
Adagio	Dover
Endeavour	Dover

# has\_docked\_at

_	<b>—</b> • •
name	port
Endeavour	Poole
Endeavour	Dover
Endeavour	Plymouth
Serenity	Plymouth
Serenity	Portsmouth
Adagio	Dover
Adagio	Plymouth

- (b) A list is a palindrome if the list is the same as its reverse. (8 marks)
  - ➤ So, [1,2,3,2,1] is a palindrome, ['a', 'b', 'b', 'a'] is a palindrome, [1] is a palindrome, [['Fred'], ['Freda'], ['Freya']] is not a palindrome.
- (i) Specify the problem of deciding if a given list is a palindrome. You may write the specification in English and/or formally with mathematical notation.

Name: palindrome

Inputs:

Preconditions:

Outputs:

Postconditions:

Q 16 (contd)

- Give your initial insight for an algorithm that uses a stack to solve the problem.
- You must use some or all of the Stack ADT's operations (pop, push, new, and is\_empty).
- ▶ You can also use any of the basic list operations:
- create an empty list, append an item, calculate the length, access an item by position (indexing), iterate over the items or over the indices, check if two lists are equal.

- ➤ Someone seeking information on a course on the TComp website will be shown a list of *prior knowledge courses* (which we will abbreviate to *prior courses* from now on).
- ► TComp needs to hold information about the courses, and which are prior courses for each other.
- So, course X has prior courses A, B and C, is TComp's way of saying that to do course X you should already know about the content of courses A and B and C.
- ► Those prior courses may also have prior courses, and a course may be a prior course for more than one other course.

Q 16 (contd)

- When a customer applies for a place on a course, they complete an application form on the website.
- This is sent electronically to a processing centre in which the applications are processed in the order they arrive.
- Courses have a limited number of places, so places are allocated to each course in the order the processed applications are received until the course is full.
- Any remaining applications are stored in case vacancies arise later.

Part 2

Soln 16

- (a) (i) O(n) two separate loops each with n operations
- There are two operations outside the loops, two operations inside each of the two loops and one operation in each of the while conditions so T(n) = 6n + 2 giving O(n)
- If you missed the operations in the while conditions then you would have T(n) = 4n + 2 still giving O(n)
- ► See What is the time complexity of Python List Reverse?, Complexity of Python Operations
- (ii) Modifier since pop() is destructive on completion of the function, the stack is empty since all items are popped off it
- (iii) To make reverse a modifier, work on a copy of the input and return the result

Soln 17

Soln 16 (contd)

(b) (i) Name: palindrome

**Inputs**: List of items  $xs = \{x_1, x_2, \dots, x_n\}$ 

**Preconditions**: The items can be compared for equality

Outputs: b, a Boolean

**Postconditions**: b is True if and only if the input is equal to its reverse, that is, a palindrome

(ii) Create empty stack s with new

Loop over the list and push each item onto the stack Loop over the list and use pop to compare each item with the item the same distance from the end

Terminate the loop if the items are not equal (return False) or we get to the empty list (return True)

Soln 16 continued on next slide

- ➤ This is equivalent to representing courses as a Directed Acyclic Graph (DAG) with nodes as courses (with descriptions) and edges indicating prior courses
  - (ii) Represent applications as list of application since the order matters
- Alternatively represent applications as a queue of application, since this would aid adding and processing order

▶ Go to Q 16

- ► Title Equivalence Problem: Does Not Compute
- Define Computability (see also Computability and Complexity) — a problem is computable if it can be solved in an effective manner by some algorithm.
- ► In the 1930s Gödel, Church and Turing provided formal models of computation — Turing machines and Lambda Calculus being the better known (but there are many others)
- Turing showed that although they look quite different, the models have exactly the same computational power
- ➤ A decision problem is a problem that can be posed as a yes-no question of the input values
- ► A decision problem is decidable if there exists an effective method for deriving the correct answer

Soln 17 (contd)

- Some decision problems are undecidable:
- ► Halting problem is there a program that can determine if any arbitrary program will halt or continue forever?
- Proof by contradiction Assume we have such a program (Turing Machine) h(f,x) that takes a program f and input x and determines if it halts or not

```
def halts(f.x):
  if f(x) terminates:
    return True
  else :
    return False
```

Soln 15 Part 2

Soln 17 (contd)

 $\triangleright$  We now use haltsto define another function r(f) that that loops forever if halts(f,f) returns True otherwise it terminates

```
def r(f) :
  if halts(f,f) :
    while True :
      continue
  else :
    return
```

- $\triangleright$  We now ask what happens if we evaluate r(r) if it terminates, it goes into a loop, and if it doesn't terminate then it stops
- Contradiction the only thing that can be wrong is our assumption that halts(f,x) exists

## Equivalence Problem

- ▶ Input: two programs *P*1 and *P*2
- Output: YES if P1 and P2 solve the same problem (same output for same input) else NO
- We show that the Equivalence Problem (EP) is not computable by reduction from the Halting Problem (HP)

Soln 15 Part 2

Soln 16 Soln 17

Soln 17 (contd)

The exam would probably not require a proof that the Equivalence Problem is undecidable but here is a proof via the Totality Problem

- Totality Problem
  - ▶ Input: program *Q*
  - Output: YES if Q terminates for all inputs else NO
- Assume we have algorithm *TP* to solve the Totality Problem
- Now reduce the Halting Problem to the Totality Problem

- Rice's Theorem all non-trivial, semantic properties of programs are undecidable. H G Rice 1951 PhD Thesis
- Equivalently: For any non-trivial property of partial functions, no general and effective method can decide whether an algorithm computes a partial function with that property.
- A property of partial functions is called trivial if it holds for all partial computable functions or for none.

Part 2 Soln 16

- - Rice's Theorem and computability theory
  - Let S be a set of languages that is nontrivial, meaning
    - there exists a Turing machine that recognizes a language in S
    - there exists a Turing machine that recognizes a language not in S
  - Then, it is undecidable to determine whether the language recognized by an arbitrary Turing machine lies in S.
  - ► This has implications for compilers and virus checkers
  - Note that Rice's theorem does not say anything about those properties of machines or programs that are not also properties of functions and languages.
  - ► For example, whether a machine runs for more than 100 steps on some input is a decidable property, even though it is non-trivial.
