

M269 Sorting

Unit 3

Phil Molyneux

5 December 2020

M269 Tutorial

Agenda

- ▶ Welcome & introductions
- ▶ *Tutorial topics:* Unit 3 Sorting Algorithms
- ▶ *Key point:* many of the sorting algorithms can be seen as variations on an abstract split/join algorithm
- ▶ *Adobe Connect* — if you or I get cut off, wait till we reconnect (or send you an email)
- ▶ *Time:* about 2 hours
- ▶ Do ask questions or raise points.
- ▶ *Source:* of slides, notes, programs and playing cards:
 - ▶ www.pmolyneux.co.uk/OU/M269FolderSync/M269TutorialNotes/M269TutorialSorting
 - ▶ *Slides:* [M269Prsntn2020JTutorialSorting.beamer.pdf](#)
 - ▶ *Notes:* [M269Prsntn2020JTutorialSorting.article.pdf](#)

M269 Tutorial

Agenda

- ▶ Motivation for studying sorting algorithms
- ▶ Taxonomy of sorting — see [Wikipedia Sorting Algorithm](#)
- ▶ Abstract comparison sort — split/join algorithm
- ▶ Insertion sort and selection sort described with split/join algorithm diagram and implemented in Python and Haskell
- ▶ Recursive and iterative versions
- ▶ Mergesort, Quicksort and Bubble sort in the same framework
- ▶ Sorting via a data structure — *Tree sort*
- ▶ Review of Web sites and sorting algorithms used in practice

Sorting Algorithms

Motivation for Studying

- ▶ From Knuth (1998, page v)
- ▶ ... virtually *every* important aspect of programming arises somewhere in the context of sorting or searching.
- ▶ How are good algorithms discovered ?
- ▶ How can given algorithms and programs be improved ?
- ▶ How can the efficiency of algorithms be analyzed mathematically ?
- ▶ How can a person choose rationally between different algorithms for the same task ?
- ▶ In what senses can algorithms be proved *best possible* ?
- ▶ How does the theory of computing interact with practical considerations ?

Sorting Algorithms

Activity 1 Card Sorting Exercise (1)

- ▶ Almost everyone has played cards and, as part of any card game, will have sorted cards in their hand
- ▶ This exercise is aimed at writing down how you sort you cards and giving these instructions to another person to follow.
- ▶ Decide on your general ordering of playing cards — you are free to set any ordering you like but here is the usual ordering for suits and values:

Clubs < Diamonds < Hearts < Spades

Two < Three < Four < Five < Six
< Seven < Eight < Nine < Ten
< Jack < Queen < King < Ace

- ▶ Write down your method for sorting cards — the method must specify how to choose a card to move and where to move it to.

Sorting Algorithms

Activity 1 Card Sorting Exercise (2)

- ▶ Take the 6 cards given below — record the order of the cards

- ▶ Using your method, sort the cards — record the order of the cards after each move of a card
- ▶ Now swap your written method and the cards in your original order with another student.
- ▶ Follow the other student's method to sort the cards and record your steps

Discussion

- ▶ Did both of you end up with the same sequence of steps?
- ▶ Did any of the instructions require human knowledge?
- ▶ General point: probably most people use some variation on *Insertion sort* or *Selection sort* but would have steps that had multiple shifts of cards.
- ▶ Note: This activity may be done on the *Whiteboard* using cards from <http://pmolyneux.co.uk/OU/M269/M269TutorialNotes/M269TutorialSorting/Cards/>

Taxonomy of Sorting Algorithms

Comparison Sorts

- ▶ Computational complexity — worst, best, average number of comparisons, exchanges and other program constructs (but see <http://www.softpanorama.org/Algorithms/sorting.shtml> for *Slightly Skeptical View*) — $O(n^2)$ bad, $O(n \log n)$ better
- ▶ Other issues: space behaviour, performance on typical data sets, exchanges versus shifts
- ▶ Abstract sorting algorithm — Following Merritt (1985, 1997) and Azmoodeh (1990, chp 9), we classify the divide and conquer sorting algorithms by easy/hard split/join
- ▶ see diagram below

Taxonomy of Sorting Algorithms

Abstract Sorting Algorithm

Sorting Algorithms

Other Classifications

- ▶ See [Wikipedia Sorting algorithm](#) for big list
- ▶ *Comparison Sorts*
 - ▶ Insertion sort, Selection sort, Merge sort, Quicksort, Bubble sort
 - ▶ Sorting via a data structure: Tree sort, Heap sort
- ▶ *Non-Comparison sorts* — distribution sorts — bucket sort, radix sort
- ▶ *Sorts used in Programming Language Libraries*
 - ▶ [Timsort](#) by Tim Peters — used in Python and Java — combination of merge and insertion sorts
 - ▶ [Haskell](#) — modified Mergesort by Ian Lynagh in [GHC](#) implementation

Recursion

Recursion and Iteration

- ▶ Many functions are naturally defined using **recursion**
- ▶ A recursive function is defined in terms of calls to itself acting on smaller problem instances along with a base case(s) that terminate the recursion
- ▶ Classic example: Factorial $n! = n \times (n - 1) \cdot \dots \cdot 2 \times 1$

```
5 def fac(n) :  
6   if n == 1 :  
7     return 1  
8   else :  
9     return n * fac(n-1)
```

- ▶ We can evaluate **fac(6)** by using a **substitution model** (section 1.1.5) for function application
- ▶ To evaluate a function applied to arguments, evaluate the body of the function with each formal parameter replaced by the corresponding actual arguments.

Recursion

Evaluation of `fac(6)`

Expression to Evaluate	Reason
<code>fac(6)</code>	Initial
→ <code>6 * fac(5)</code>	line 8
→ <code>6 * (5 * fac(4))</code>	line 8
→ <code>6 * (5 * (4 * fac(3)))</code>	line 8
→ <code>6 * (5 * (4 * (3 * fac(2))))</code>	line 8
→ <code>6 * (5 * (4 * (3 * (2 * fac(1)))))</code>	line 8
→ <code>6 * (5 * (4 * (3 * (2 * 1))))</code>	line 6
→ 720	Arithmetic

- ▶ This occupies more space in the process of evaluation since we cannot do the multiplications until we reach the base case of `fac()`
- ▶ This is a *recursive* function and a linear recursive process
- ▶ *Implemented* in Python (and most imperative languages) with a *stack* of function calls
- ▶ We can define an equivalent *factorial* function that produces a different process

Recursion

Iterative Factorial

```
24 def facIter(n) :  
25     return accProd(n,1)  
  
27 def accProd(n,x) :  
28     if n == 1 :  
29         return x  
30     else :  
31         return accProd(n-1, n * x)
```

- ▶ `facIter()` use `accProd()` to maintain a running product and accumulate the final result to return
- ▶ We can display the evaluation of `facIter(6)` using the substitution model

Recursion

Evaluation of `facIter(6)`

Expression to Evaluate	Reason
<code>facIter(6)</code>	Initial
→ <code>accProd(6, 1)</code>	line 25
→ <code>accProd(5, 6 * 1)</code>	line 30 & (*)
→ <code>accProd(4, 5 * 6)</code>	line 30 & (*)
→ <code>accProd(3, 4 * 30)</code>	line 30 & (*)
→ <code>accProd(2, 3 * 120)</code>	line 30 & (*)
→ <code>accProd(1, 2 * 360)</code>	line 30 & (*)
→ 720	line 28 & (*)

- ▶ This occupies constant space — at each stage all the variables describing the state of the calculation are in the function call
- ▶ This is a recursive program and an iterative process
- ▶ We are assuming the multiplication is evaluated at each function call (strict or eager evaluation)
- ▶ Also referred to as *tail recursion* — we need not build a stack of calls

Recursion and Iteration

Iterative Factorial Exercises

- ▶ Write a version of the *factorial* function using a **while** loop in Python
- ▶ Write a version of the *factorial* function using a **for** loop in Python

Recursion and Iteration

Iterative Factorial Exercises — Solutions

► *Factorial* function using a **while** loop in Python

```
46 def facWhile(n) :  
47     x = 1  
  
49     while n > 1 :  
50         x = n * x  
51         n = (n - 1)  
  
53     return x
```

► *Factorial* function using a **for** loop in Python

```
57 def facFor(n) :  
58     x = 1  
  
60     for i in range(n,0,-1) :  
61         x = i * x  
  
63     return x
```

Recursion

Tail Recursion and Iteration

- ▶ When the [structured programming](#) ideas emerged in the 1960s and 1970s the languages such as C and Pascal implemented recursion by always placing the calls on the stack — Python follows this as well
- ▶ This means the in those languages they have to have special constructs such as [for](#) loops, [while](#) loops, to express iterative processes without recursion
- ▶ A [for](#) loop is syntactically way more complicated than a recursive definition
- ▶ Some language implementations (for example, Haskell) spot tail recursion and do not build a stack of calls
- ▶ You still have to write your recursion in particular ways to allow the compiler to spot such optimisations.

Recursion

Structured Programming, GOTO and Recursion

- ▶ Bohm & Jacopini (1966) showed that structured programming with a combination of sequence, selection, iteration and procedure calls was **Turing complete** (see Unit 7)
- ▶ In the late 1980s two books came out that were particularly influential:
- ▶ Abelson and Sussman (1984, 1996) *Structure and Interpretation of Computer Programs* (known as SICP) which was the programming course for the first year at MIT,
- ▶ Bird and Wadler (1988, 1998, 2014) *Introduction to Functional Programming* which was the the programming course for the first year at Oxford.
- ▶ See **SICP online** and **Section 1.2 Procedures and the Process They Generate**

Recursion

Structured Programming, GOTO and Recursion (2)

- ▶ Dijkstra (1968) *Go To Statement Considered Harmful* illustrates a debate on structured programming
- ▶ The [von Neumann computer architecture](#) takes the memory and state view of computation as in Turing m/c
- ▶ [Lambda calculus](#) is equivalent in computational power to a Turing machine (Turing showed this in 1930s) but efficient implementations did not arrive until 1980s
- ▶ Functional programming in [Lisp](#) or [APL](#) was slow
- ▶ Alan Perlis (1982) *Epigrams on Programming*: [Functional programmers] know the value of everything but the cost on nothing
- ▶ Erik Meijer (1991) *Recursion is the GOTO of functional programming*
- ▶ Leading to common patterns of higher order functions, [map](#), [filter](#), [fold](#) and polymorphic data types

Split/Join Sorting Algorithms

Example Algorithms & Implementation

- ▶ Insertion Sort
- ▶ Selection Sort
- ▶ Merge Sort
- ▶ Quicksort
- ▶ Bubble Sort
- ▶ Implementations in Python, recursive and non-recursive
- ▶ Implementations in Haskell — for comparison, optional
- ▶ Sorting via data structure — Treesort, Heap Sort

Python Rewritten

► In the style of the abstract algorithm

```
20 def insSort01(xs) :
21     if len(xs) <= 1 :
22         return xs
23     else :
24         (xs1,xs2) = insertionSplit(xs)
25         ys1 = insSort01(xs1)
26         ys2 = insSort01(xs2)
27         ys = insertionJoin(ys1,ys2)
28         return ys

30 def insertionSplit(xs) :
31     (xs1,xs2) = (xs[0:1],xs[1:])
32     return (xs1,xs2)

34 def insertionJoin(ys1,ys2) :
35     if ys2 == [] :
36         return ys1
37     elif ys1[0] <= ys2[0] :
38         return ys1 + ys2
39     else :
40         return ys2[0:1] + insertionJoin(ys1,ys2[1:])
```

Insertion Sort

Haskell Implementation (1)

```
1 module M269TutorialSorting where
2 import Data.List
3 import Data.Maybe
```

1. A Haskell script starts with a module header which starts with the reserved identifier, `module` followed by the module name, `M269TutorialSorting`
2. The module name must start with an upper case letter and is the same as the file name (without its extension of `.lhs`)
3. Haskell uses *layout* (or the *off-side rule*) to determine scope of definitions, similar to Python
4. The body of the module follows the reserved identifier `where` and starts with two `import` declarations
5. These import the built-in libraries `Data.List` and `Data.Maybe`

Insertion Sort

Haskell Implementation (2)

```
5  insSort [] = []
6  insSort [x] = [x]
7  insSort (x : xs) = ins x (insSort xs)

9  ins x [] = [x]
10 ins x (y:ys)
11   = if x <= y
12     then x:y:ys
13     else y : (ins x ys)
```

- ▶ For *structured English*, I have used a subset of *Haskell* (<http://haskell.org>) — in the code above:
- ▶ *insSort* and *ins* are function defined by several equations
- ▶ We use *indentation* to determine scope — see Landin (1966) and Python (see [Python Tutorial: Introduction: First Steps Towards Programming](#))

Insertion Sort

Haskell Implementation (3)

- ▶ Function application is denoted by juxtaposition and is more tightly binding than (almost) anything else
 - ▶ we write `f x` and not `f (x)`
 - ▶ `f x y` means `(f x) y`

This notational convention has huge advantages — discuss and also see

http://en.wikipedia.org/wiki/Curried_function and <http://slid.es/gsklee/functional-programming-in-5-minutes> (which does it in JavaScript, worth a look)

- ▶ Lists are denoted with brackets `[1,2,3]`, the empty list is `[]`
- ▶ `(:)` is the operator that prefixes an element to a list, `1:[2,3] == [1,2,3]`
- ▶ Parentheses over-ride precedence

Activity 2

Trace an Evaluation — Haskell

- Evaluation of `insSort [3,0,1,8,7]`

Activity 2

Trace an Evaluation — Haskell

► Evaluation of `insSort [3,0,1,8,7]`

Expression to Evaluate	Reason
<code>insSort [3,0,1,8,7]</code>	Initial
→ <code>ins 3 (insSort [0,1,8,7])</code>	line 7
→ <code>ins 3 (ins 0 (insSort [1,8,7]))</code>	line 7
→ <code>ins 3 (ins 0 (ins 1 (insSort [8,7])))</code>	line 7
→ <code>ins 3 (ins 0 (ins 1 (ins 8 (insSort [7])))</code>	line 7
→ <code>ins 3 (ins 0 (ins 1 (ins 8 [7])))</code>	line 6
→ <code>ins 3 (ins 0 (ins 1 (7:(ins 8 []))))</code>	line 13
→ <code>ins 3 (ins 0 (ins 1 (7:[8])))</code>	line 9
→ <code>ins 3 (ins 0 (ins 1 [7,8]))</code>	(:) operator
→ <code>ins 3 (ins 0 (1:7:[8]))</code>	line 12
→ <code>ins 3 (ins 0 [1,7,8])</code>	(:) operator
→ <code>ins 3 (0:1:[7,8])</code>	line 12
→ <code>ins 3 [0,1,7,8]</code>	(:) operator
→ <code>0:(ins 3 [1,7,8])</code>	line 13
→ <code>0:(1:(ins 3 [7,8]))</code>	line 13
→ <code>0:(1:(3:7:[8]))</code>	line 12
→ <code>[0,1,3,7,8]</code>	(:) operator

- Note that the evaluation consumes more space in the process of evaluation;
- also note that you need to be careful with the brackets when doing an evaluation like this by hand.

→ <code>ins(3, ins(0, ([1] + [7,8])))</code>	line 13
→ <code>ins(3, ins(0, [1,7,8]))</code>	(+) operator
→ <code>ins(3, ([0] + [1,7,8]))</code>	line 13
→ <code>ins(3, [0,1,7,8])</code>	(+) operator
→ <code>[0] + (ins 3 [1,7,8])</code>	line 15
→ <code>[0] + ([1] + (ins 3 [7,8]))</code>	line 15
→ <code>[0] + ([1] + ([3] + ([7,8])))</code>	line 13
→ <code>[0,1,3,7,8]</code>	(+) operator

- Note that the evaluation consumes more space in the process of evaluation;
- also note that you need to be careful with the brackets when doing an evaluation like this by hand.

Insertion Sort

Non-recursive Implementation

- The non-recursive version of *Insertion* sort takes each element in turn and inserts it in the ordered list of elements before it.

```
for index = 1 to (len(xs)-1) do
  insert xs[index] in order in xs[0..index-1]
```

- Here is a Python implementation of the above (based on Miller and Ranum (2011, page 215)).

```
42 def insertionSort(xs) :
43     for index in range(1, len(xs)) :
44         currentValue = xs[index]
45         position = index
46         while (position > 0) and xs[position - 1] > currentValue :
47             xs[position] = xs[position - 1]
48             position = position - 1
50     xs[position] = currentValue
```

Activity 3

Selection Sort

Abstract Sorting Algorithm Diagram

Selection Sort

Haskell Implementation

```
15 selSort [] = []
16 selSort [x] = [x]
17 selSort xs = minItem : selSort (xs \\ [minItem])
18 where
19     minItem = minimum xs
```

- ▶ Explanation of the above:
- ▶ (`\\`) is the *list difference* operator
- ▶ `[2,1,3,1] \\ [1] == [2,3,1]`
- ▶ `minimum` is the Haskell built in function that takes a list and returns the smallest item.
- ▶ See the `Data.List` library
- ▶ Exercise: produce your own implementation of `minimum` — remember to give it a different name

Activity 4 — Selection Sort

Sorting via a Data
Structure — Heap
Sort

Selection Sort

Non-recursive Implementation

- The non-recursive version of *Selection* sort takes each position of the list in turn and swaps the element at that position with the minimum element in the rest of the list from that position to the end of the list.

```
for fillSlot = 0 to (len(xs) - 2) do
  find the minimum of
    xs[fillSlot+1]..xs[len(xs) - 1]
  and swap with xs[fillSlot]
```

Selection Sort

Python Non-recursive Implementation

- ▶ Here is a Python implementation of the above (based on Miller and Ranum (2011, page 211) but selecting the smallest first not largest, influenced by http://rosettacode.org/wiki/Sorting_algorithms/Selection_sort#PureBasic).
- ▶ Note that here we indent by 2 spaces and use the Python idiomatic *simultaneous assignment* to do the swap in line 71

```
63 def selectionSort(xs) :  
64     for fillSlot in range(0, len(xs)-1) :  
65         minIndex = fillSlot  
66         for index in range(fillSlot+1, len(xs)) :  
67             if xs[index] < xs[minIndex] :  
68                 minIndex = index  
  
70         # if fillSlot != minIndex: # only swap if different  
71         xs[fillSlot], xs[minIndex] = xs[minIndex], xs[fillSlot]
```

Selection Sort

Non-recursive Implementation

- The non-recursive version of *Selection* sort in Miller & Ranum sorts in ascending order but takes each position of the list in turn from the right end and swaps the element at that position with the maximum element in the rest of the list from the beginning of the list to that position. (Miller and Ranum (2011, page 211))

```
for fillSlot = len(xs) - 1 down to 1 do
  find the maximum of
    xs[0] .. xs[fillSlot]
  and swap with xs[fillSlot]
```

Sort

Selection Sort

Python Non-recursive Implementation

- Here is a Python implementation of the above (based on Miller and Ranum (2011, page 211) selecting the largest first.

```
73 def selSortAscByMax(xs) :  
74     for fillSlot in range(len(xs) - 1, 0, -1) :  
75         maxIndex = 0  
76         for index in range(1, fillSlot + 1) :  
77             if xs[index] > xs[maxIndex] :  
78                 maxIndex = index  
  
80     temp = xs[fillSlot]  
81     xs[fillSlot] = xs[maxIndex]  
82     xs[maxIndex] = temp
```

- Note that both Python non-recursive versions work by side-effect on the input list — they do not return new lists.

Activity 5

Finding the Non-Recursive Algorithm

- For *Insertion Sort* and *Selection Sort* discuss how the non-recursive case can be found by considering the recursive case and doing the algorithm in place.

Haskell Implementation

Code Description

- ▶ Reserved words and built in function are in **blue**
- ▶ **take n xs** returns the first **n** of **xs** as a new list
- ▶ **div** is the integer division function, the back quotes make it an infix operator
- ▶ **3 'div' 2 == div 3 2 == 1**
- ▶ In **mergeJoin**, if the boolean expression following a vertical bar (**|**) evaluates to **True** then the value of the left hand side is given by the expression on the right of the following “=” — the lines are known as *guards* and are evaluated in turn until one is found to be true (**otherwise** is a nickname for **True**)
- ▶ We have **mergeSplit1** and **mergeSplit2** to illustrate choices.
- ▶ The code for **mergeSplit1** is given below — it splits the list with just one traversal of the list

Merge Sort

Python Code Description

- ▶ `_` is how the `listings` package shows spaces in strings by default (read the manual)
- ▶ `//` is the Python integer division operator
- ▶ `aList[start:stop:step]` is a *slice* of a list — see [Python Sequence Types](#) — slice operations return a new list (van Rossum and Drake, 2011a, page 19) so `xs[:]` returns a copy (or clone) of `xs` — if any of the indices are missing or negative than you have to think a bit (or read the manual)
- ▶ In Python you really do need to be aware when you are working with values or references to objects.

Merge Sort

Python In-Place (3)

- A listing of the output of `mergeSortInPlace(xsc)` below is given in the article version of these notes

```
>>> from SortingPython import *
>>> xs = [3,0,1,8,7,2,5,4,9,6]
>>> xsc = xs[:]
>>> mergeSortInPlace(xsc)
Splitting  [3, 0, 1, 8, 7, 2, 5, 4, 9, 6]
#
# lines removed
#
Merging  [0, 1, 3, 7, 8] , [2, 4, 5, 6, 9]
to [0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

Quicksort

Abstract Algorithm

- ▶ *Quicksort Split* Choose an item in the list to be the *pivot* item; *xs1* comprises items in the list less than the pivot plus the *pivot*; *xs2* comprises items in the list greater than or equal to the *pivot*.
- ▶ *Quicksort Join* just append the sorted *xs1* and the sorted *xs2* together as the output list

Quicksort

Abstract Sorting Algorithm Diagram

Quicksort

Haskell Implementation

```
47 quickSort1 [] = []
48 quickSort1 (x:xs)
49   = quickSort1 [y | y <- xs, y < x]
50     ++ [x]
51     ++ quickSort1 [y | y <- xs, y >= x]
```

- ▶ This uses the Haskell version of the **list comprehension notation**
- ▶ Based on classical set notation and originally implemented in *Miranda* out of David Turner in 1983–6 (see <http://miranda.org.uk>)
- ▶ This idea is available in Python but in a slightly different syntax
- ▶ ++ is the list append operator — denoted $\oplus$ in various courses and texts

List Comprehensions

In Haskell and Python

- ▶ Haskell 2010 Language Report section 3.11 *List Comprehensions*
- ▶ $[e \mid q_1, \dots, q_n], n \geq 1$ where q_i qualifiers are either
 - ▶ *generators* of the form $p \leftarrow e$ where p is a pattern of type t and e is an expression of type $[t]$
 - ▶ *local bindings* that provide new definitions for use in the generated expression e or subsequent boolean guards and generators
 - ▶ *boolean guards* which are expressions of type `Bool`
- ▶ Python Language Reference section 6.2.4 *Displays for lists, sets and dictionaries* and section 6.2.5 *List displays*
- ▶ `[ expr for target in list ]` — simple comprehension
- ▶ `[ expr for target in list if condition ]` — filters
- ▶ `[ expr for target1 in list1 for target2 in list2 ]` — multiple generators

Quicksort

Python In-Place (1)

- ▶ The in-place version of Quick sort works by partitioning a list in place about a value **pivotvalue**: (Azmoodeh, 1990, page 259–266)

(1) Scan from the left until

- ▶ `alist[leftmark] >= pivotvalue`

(2) Scan from the right until

- ▶ `alist[rightmark] < pivotvalue`

(3) Swap `alist[leftmark]` and `alist[rightmark]`

(4) Repeat (1) to (3) until scans meet

Quicksort

Python In-Place (4)

- ▶ The `(\)` is enabling a statement to span multiple lines — see Lutz (2009, page 317), Lutz (2013, page 378)
- ▶ for a language that uses the *offside rule* why do we need to do this?
- ▶ Note that using `(\)` to create continuations is *frowned on* Lutz (2009, page 318), Lutz (2013, page 379)
- ▶ the authors should have put the entire boolean expression inside parentheses `()` so that we get implicit continuation.
- ▶ This is not mentioned explicitly in the *Style Guide for Python Code* <http://www.python.org/dev/peps/pep-0008/> but it does explicitly mention using Python's implicit line joining with layout guidelines.

Bubble Sort

Abstract Algorithm

- ▶ *Bubble sort* is rather like the *Hello World* program of sorting algorithms — we have to include it even it isn't very useful in practice.
- ▶ It can be thought of as an in-place version of Selection sort
- ▶ In the implementations below, in each pass through the list, the next highest item is moved (bubbled) to its proper place.
- ▶ OK, I should have written it to bubble the smallest the other way to be consistent with the implementations of Selection sort above.

Bubble Sort

Haskell

- ▶ Here is a naive version (based on http://rosettacode.org/wiki/Sorting_algorithms/Bubble_sort#Haskell)
- ▶ it is *naive* because it does the check for changes in a simple way.
- ▶ See the above Web site for more sophisticated versions

```
53 bubbleSort xs
54   = if (ts == xs) then ts else (bubble ts)
55   where
56     ts = bubble xs

58 bubble [] = []
59 bubble [x] = [x]
60 bubble (x1:x2:xs)
61   | x1 > x2 = x2 : (bubble (x1 : xs))
62   | otherwise = x1 : (bubble (x2 : xs))
```

Bubble Sort

Haskell Code Description

- ▶ The expression `(x1:x2:xs)` denotes a list of at least two items whose first two items are `x1` and `x2` and the rest of the list is `xs`
- ▶ The third equation defining `bubble` uses *boolean guards* starting with `(|)` rather than a *conditional expression* (`if ... then ... else ...`)
- ▶ it could be written the other way and remove the need to understand this style of function declaration but this is a frequently used style in Haskell

Bubble Sort

Python

- ▶ Here is a Python implementation from Miller and Ranum (2011, pages 207–210)
- ▶ it does not test if there have been no swaps but does use some knowledge of the algorithm by reducing the pass length by one each time (which the Haskell one did not do)

```
203 def bubbleSort(xs) :  
204     for passNum in range(len(xs) - 1, 0, -1) :  
205         for i in range(passNum) :  
206             if xs[i] > xs[i+1] :  
207                 xs[i], xs[i+1] = xs[i+1], xs[i]
```

- ▶ Note that `range()` is a built-in function to Python that is used a lot
- ▶ Read the documentation at [Section 4.6.6 Ranges](#)
- ▶ Remember that `range(5)` means `[0,1,2,3,4]` (not `[0,1,2,3,4,5]` or `[1,2,3,4,5]`)

What Next ?

Topics in Units 3 and 4

- ▶ Binary trees, Binary heaps and Heap sort
- ▶ Searching — searching for patterns, string searches
- ▶ Hashing and hash tables
- ▶ Binary search trees, height balanced binary search trees, AVL trees

Tree Sort

Python (2)

- ▶ This is from `SortingPython.py`
- ▶ Reserved identifiers are shown in `this color`
- ▶ User defined data constructors such as `NodeBT` and `EmptyTreeBT` are shown in `that color`
- ▶ `NodeBT` is a named tuple with named fields — a *quick and dirty* object
- ▶ `makeEmptyBT`, `makeBT` are *constructor* functions — we could have used the raw named tuple and `None` but the discipline is good for you
- ▶ `isEmptyBT` uses the `is` operator for identity check (not `(==)`)
- ▶ **Health Warning:** these notes may not be totally consistent with syntax colouring.

Tree Sort

Python (3)

- ▶ `insertListBST` and `insertBST` insert a list of items into a Binary Search Tree
- ▶ To be consistent, we should have used the constructor functions to hide the implementation.

```
274 def insertBST(x,t) :
275     if isEmptyBT(t) :
276         return NodeBT(x,EmptyTreeBT,EmptyTreeBT)
277     else :
278         y = t.dataBT
279         if x < y :
280             return NodeBT(y, insertBST(x,t.leftBT),t.rightBT)
281         elif x > y :
282             return NodeBT(y, t.leftBT, insertBST(x,t.rightBT))
283         else :
284             return t
286 def insertListBST(t,xs) :
287     if xs == [] :
288         return t
289     else :
290         return insertListBST(insertBST(xs[0],t),xs[1:])
```

Example Tree Sort 1

Insert [3,0,1,8,7,2,5,4,9,6] into `EmptyTreeBT`

`egTreeTest`

- ▶ The in-order traversal of `egTreeTest` outputs
- ▶ [0,1,2,3,4,5,6,7,8,9]

Tree Sort

Haskell (1)

```
64 data BinTree a = EmptyTreeBT
65                 | NodeBT a (BinTree a) (BinTree a)
66                 deriving (Eq,Ord,Show,Read)

68 -- BSTree is an alias for BinTree,
69 -- we have to enforce the Binary Search Tree property

71 type BSTree a = BinTree a
```

- ▶ The code starting with **data** (line 64) is an *Algebraic Datatype* declaration. Algebraic datatypes allow you just to name things and use them in your program
- ▶ Meta-magic and avoids ever needing to use pointers
- ▶ For a description see [Algebraic data type](#) and Marlow and Peyton Jones (2010, section 4.2.1)
- ▶ `--` comments out a line

Tree Sort

Haskell (2)

- ▶ **BinTree** is the name of the type and **EmptyTreeBT**, **NodeBT** are the two *data constructors*
- ▶ **a** is a *type variable* — that is, a variable that ranges over types (not values). It could be any type (subject to any restrictions we place on it): primitive types such as **Int**, **Bool**, built-in structured types such as tuples or list, or other user defined types
- ▶ The constructor **EmptyTreeBT** is to represent an empty tree (took ages to think of that name)
- ▶ The constructor **Node** takes three arguments: the first is of type **a** and is meant to represent the data stored at a node, the second and third are of type **BinTree a** and indicate the left and right sub trees

Tree Sort

Haskell (3)

- Here is a sample tree with 51 at the root and left and right subtree with 26 and 69 at their roots

```
NodeBT 51  
  (NodeBT 26 EmptyTreeBT EmptyTreeBT)  
  (NodeBT 69 EmptyTreeBT EmptyTreeBT)
```

Here is the usual diagram of this tree (with the empty trees labelled as E):

Tree Sort

Haskell (4)

- ▶ The `deriving (Eq,Ord,Show,Read)` part of the declaration produces *derived instances* for `BinTree` is the type classes for equality (`Eq`), ordering (`Ord`), printing (`Show`) and reading from files (or standard input) (`Read`)
- ▶ Equality as a derived instance is just lexicographic — that is, two trees are equal if and only if they look the same
- ▶ `Show` and `Read` do the *fairly* obvious thing — the above example would be printed or read as you see it above.
- ▶ The `(|)` is just the syntax separating the two constructors
- ▶ The line starting `type` (line 71) is a *type synonym* declaration — this is not needed apart from making the code a bit more readable (to distinguish Binary Search Trees from other Binary Trees)

Tree Sort

Haskell (6)

- ▶ The line starting `insertBST ::` (line 72) is a *Type Signature* which specifies the type of the function `insertBST`
- ▶ `Ord a` is a *context* for the type following `=>` with one *class assertion* — it restricts the type variable `a` to be a member of the `Ord` type class
- ▶ `BSTree a -> a -> BSTree a` says that `insertBST` takes a binary tree and an item and returns a binary tree.
- ▶ The function type operator `->` is right associative (to match left association of function application) — see Lee (2013).

Tree Sort

Haskell (7)

```
89 inorderBST :: BSTree a -> [a]
90 inorderBST EmptyTreeBT = []
91 inorderBST (NodeBT x leftT rightT)
92   = (inorderBST leftT) ++ [x] ++ (inorderBST rightT)

94 treeSort :: Ord a => [a] -> [a]
95 treeSort xs = inorderBST (insertListBST EmptyTreeBT xs)
```

- ▶ The `++` is the list append operator
- ▶ `treeSort` takes a list `xs` and uses `insertListBST` to insert the list into `EmptyTreeBT` and then `inorderBST` to traverse the tree

Tree Sort

Haskell (8) Alternative Definitions

► Alternative tree building bracketing from the right

```
96 insertBST01 :: (Ord a) => a -> BSTree a -> BSTree a

98 insertBST01 x EmptyTreeBT
99   = NodeBT x EmptyTreeBT EmptyTreeBT

101 -- Note that insertBST01 does not accept duplicate keys,
102 -- see \citet[page 271]{millar:2011python}

104 insertBST01 x (NodeBT y leftT rightT)
105   | x < y  = NodeBT y (insertBST01 x leftT) rightT
106   | x > y  = NodeBT y leftT (insertBST01 x rightT)
107   | x == y = NodeBT y leftT rightT

109 insertListBST01 :: (Ord a) => BSTree a -> [a] -> BSTree a
110 insertListBST01 t [] = t
111 insertListBST01 t (x:xs)
112   = insertBST01 x (insertListBST01 t xs)
```

Tree Sort

Haskell (9) Alternative Definitions

- ▶ Some more idiomatic Haskell using *higher order functions*
- ▶ `(.)` is the *function composition* operator
- ▶ `(f . g) x = f (g x)`
- ▶ `foldl` and `foldr` capture common patterns of recursion on lists

```
113 treeSort01 :: Ord a => [a] -> [a]
114 treeSort01 = inorderBST . (insertListBST EmptyTreeBT)
115 -- point free style requires explicit type signature
116 -- because of the monomorphism restriction

118 insertListBSTa :: (Ord a) => [a] -> BSTree a
119 insertListBSTa xs = foldl insertBST EmptyTreeBT xs

121 insertListBST01a :: (Ord a) => [a] -> BSTree a
122 insertListBST01a xs = foldr insertBST01 EmptyTreeBT xs
```

Tree Sort

Haskell (10)

$\text{foldl } (\oplus) \ z \ [x_1, x_2, \dots, x_n]$
→ $(\dots((z \oplus x_1) \oplus x_2) \oplus \dots) \oplus x_n$
 $\text{foldr } (\oplus) \ z \ [x_1, x_2, \dots, x_n]$
→ $x_1 \oplus (x_2 \oplus \dots \oplus (x_n \oplus z) \dots)$

► Examples

- $\text{sum } xs = \text{foldr } (+) \ 0 \ xs$
- $\text{product } xs = \text{foldr } (*) \ 1 \ xs$
- $\text{concat } xss = \text{foldr } (++) \ [] \ xss$
- Higher order functions tend to get used a lot in idiomatic functional programming
- *Higher order functions* take functions as arguments and/or return functions as results

160           (NodeBT 8 EmptyTreeBT EmptyTreeBT))
161         EmptyTreeBT)
```

Example Tree Sort 2

Insert [3,0,1,8,7,2,5,4,9,6] into **EmptyTreeBT**

egTreeTest01a

- ▶ **egTreeTest01a** is built with **foldr**
- ▶ The in-order traversal of **egTreeTest01a** outputs
- ▶ **[0,1,2,3,4,5,6,7,8,9]**

Heap Sort

Abstract Algorithm

- ▶ A **Binary Heap** is a **Heap** using a binary tree with two additional properties:
 - ▶ *Compact shape* A binary heap is a **complete binary tree** — every level, except possibly the last, is completely filled and all nodes in the last level are as far left as possible.
 - ▶ *Heap property* All nodes are either greater than or equal to or less than or equal to each of its children.
- ▶ In many implementations, the Binary Heap is implemented as an implicit data structure using an array
- ▶ The array is a breadth first listing of the nodes
- ▶ New nodes can be added in the *next* position in the implicit tree and then percolated or sifted up the tree to its (or a) correct position.
- ▶ If the root of the tree is deleted then the *last* node is promoted to the root and percolated or sifted down the tree to a correct place

Heaps

Implementations and Applications

- ▶ There are lots of varieties of **heaps**
- ▶ Used later in M269 for **Priority queues**
- ▶ As well as Miller and Ranum and the M269 material, see
 - ▶ **Comparison of Priority Queue implementations in Haskell**
 - ▶ **Louis Wasserman: Playing with Priority Queues**
- ▶ TODO: typeset the Python and Haskell for this
