### M269 Tutorial

#### Agenda & Aims

- 1. Welcome and introductions
- 2. Material on Binary Trees and Searching
- 3. Implementation in Python
- 4. Learning themes:
  - Evaluation of expressions
  - Synthesising an algorithm from an initial idea
- 5. To cover some of
  - Binary Trees
  - Binary Search Trees
  - ► Height Balanced (AVL) Trees
- 6. Questions & discussion (at any point)
- Adobe Connect if you or I get cut off, wait till we reconnect (or send you an email)
- 8. Source: of slides, notes, programs:

pmolyneux.co.uk/OU/M269FolderSync/M269TutorialSamples2023/M269TutorialBinaryTreesCmntry2023/

Commentary 6

Future Work

Phil Molvneux

► There is a lot more material in these slides/notes than we can cover in the available time, so I will cover:

- (1) Binary Tree terminology and representation some choices
- (2) Tree traversal depth first recursive
- (3) Tree traversal breadth first recursive first, transformed to the usual iterative version
  - ► These notes are as much about recursion as Binary trees — the notes give several examples of evaluations and what to do when you make a mistake
- (4) Binary search trees deleting a node choices
- (5) AVL or height balanced trees brief introduction Health Warning These notes contain some material that is not part of M269 but is present for interest

#### Materials

- From the Web link to the folder containing the tutorial materials you should find:
- ► File with name ending .beamer.pdf the slides
- ► File with name ending .article.pdf the notes version
- ► Table of contents in the slides this is a clickable sidebar; in the notes it is an expanded list of sections with links from the end of sections
- ► Indices the notes version has an index of the Python code and the diagrams
- References the notes version has references which have back references to the pages where the reference is cited

- Name Phil Molyneux
- Background
  - Undergraduate: Physics and Maths (Sussex)
  - Postgraduate: Physics (Sussex), Operational Research (Brunel), Computer Science (University College, London)
  - Worked in Operational Research, Business IT, Web technologies, Functional Programming
- First programming languages Fortran, BASIC, Pascal
- Favourite Software
  - Haskell pure functional programming language
  - ► Text editors TextMate, Sublime Text previously Emacs
  - ▶ Word processing in LATEX all these slides and notes
  - ► Mac OS X
- Learning style I read the manual before using the software

#### Introduction

- The tree data structure is the most widely used non-linear structure in many algorithms.
- Almost all algorithms that take logarithmic time,  $O(\log n)$ , do so because of an underlying tree structure.
- Common examples
- ▶ Binary search tree this is used in many search applications
- Huffman coding tree used in compression algorithms in, for example, JPEG and MP3 files
- ► Heaps used to implement priority queues
- B-trees generalisation of Binary search trees used in databases.

#### **Terminology**

- Binary Tree definition a Binary tree is either
  - ▶ an Empty Tree or
  - ▶ a Node with an item and two subtrees
  - One subtree is designated a left subtree and the other a right subtree
- Note that this is a recursive or inductive definition this is very common in programming.
- Can also define trees as graphs without cycles see graph notes

#### Other Recursive Data Structures

- Other examples of recursive or inductively defined data structures we have seen include:
- A List is either
  - ► an Empty List or
  - ▶ an Item followed by the rest of the list
- ► A Stack is either
  - ► an Empty Stack or
  - ▶ the Top item followed by the rest of the stack
- ► In each case the recursive nature of the data structure definition frequently gives a clue about how to write a recursive program for a computational problem.

#### **Terminology**

- Children subtrees of a node that are not empty
- Leaves nodes with two empty subtrees
- ► Full Binary Tree every node other than the leaves has two non empty subtrees
- ▶ Perfect Binary Tree all leaves are at the same level (or depth) children
- Complete Binary Tree every level, except possibly the last, is completely filled, and all nodes are as far left as possible — used for Binary Heap
- ► **Health Warning:** the terminology varies from text to text and between graph theory in mathematics and computing.

Python Representation from 2021J (1)

- In 2021 M269 revision the Binary Tree Abstract Data
- Type (ADT) is represented by the following Python Class ▶ The code is in the M269 Jupyter Notebooks and the provided file m269\_trees.py
- The code is reproduced in the file M269BinaryTrees2021J.py but, for brevity, without the docstrings

```
10 class Tree :
    def __init__(self) :
      self.root = None
13
      self.left = None
      self.right = None
15
17 def is_empty(tree: Tree) -> bool :
    return (tree.root == tree.left == tree.right
            == None)
19
21 def join(item: object, left: Tree, right: Tree) -> Tree :
    tree = Tree()
    tree.root = item
23
   tree.left = left
   tree.right = right
25
```

Commentary 1

Agenda Adobe Connect

Examples

Alternate

Operations

Depth First

Representation

**Binary Trees** 

Terminology

- ► This representation works (see the M269 book) but has the slight disadvantage in the it has no default print representation that is useful
- For example, here is what happens when we attempt to print a very small tree — threeBT is the same as THREE in the chapter

```
Python3>>> threeBT = join(3,Tree(),Tree())
Python3>>> threeBT
<M269BinaryTrees2021J.Tree object at 0x10095a0a0>
Python3>>>
```

We could write a method to implement a print representation of an instance of the class Tree() but that might be a lot of code Binary Trees

Python Representation from 2021J (2)

- The main point of having an Abstract Data Type (ADT) is we can swap out the underlying implementation for another one
- This might be done for efficiency reasons but here we do it to get an underlying type with a default print representation
- All we have to do is keep operations which provide access to the underlying representation
- This is called a learning opportunity!

#### Python Alternate Representation (1)

- We first list the operations which will (or might) need to have direct access to the underlying representation
- Make an empty tree
- Construct a new tree from an item and two trees
- Query if a given tree is an empty tree
- Given a tree, return the left sub tree
- Given a tree, return the right sub tree
- Find the height of a tree
- Find the size of a tree
- The last two do not need access to the underlying representation (we can calculate the size and height with just the other operations) but as we will see later, we might give access for efficiency reasons

Python Alternate Representation (3)

- The functions labelled Constructor, Inspector, Destructor are operations that have direct access to the underlying representation
- sizeBT() and heightBT() are just ordinary operations in this version of the Tree ADT but for efficiency reasons they may become Inspectors in a later version

Python Alternate Representation (4)

- ► We shall represent nodes by a named tuple a *quick* and dirty object recommended by Guido van Rossum (author of the Python programming language).
- namedtuple() is a factory function for creating tuple subclasses with named fields
- ▶ It is imported from the collections module.
- It has a default print representation

```
from collections import namedtuple

EmptyBT = namedtuple('EmptyBT',[])

NodeBT = namedtuple('NodeBT'
, ['dataBT','leftBT','rightBT'])
```

```

Python Alternate Representation (5)

- The Python code above is in the file Python/M269TutorialBinaryTrees2022.py
- The line numbers in the margin correspond to the line numbers in the file.
- Notational convention:
- Python reserved identifiers are shown in this color
- Python buit-in functions in this color
- User defined data constructors and functions such as NodeBT and EmptyBT are shown in that color
- Health Warning: these notes may not be totally consistent with syntax colouring.

es 46/338

- We declare the Python type for a Union type since a Tree is either an empty tree or a non-empty tree
- This is venturing into some of the areas of Python Type Annotations that feel rather awkward but we shall use them in a simple way
- Remember that the Python interpreter only checks the type annotations for validity but not for correctness they just have to look like proper types but the processor does *not* check them

```
# Tree type

from typing import TypeVar,Union,NewType

T = TypeVar('T')
Tree = NewType('Tree',Union[EmptyBT,NodeBT]).
```

Python Alternate Representation (7)

- Note that using namedtuple means that all items are assumed to have Any types (see mypy: Named tuples)
- You could use NamedTuple which is a typed version of namedtuple but this would be getting a lot more complicated than types as used in M269
- in particular you would get involved in specifying user-defined generic types and forward references (since the Tree data type is recursive)
- We could have avoided Union by just having NodeBT and representing an empty tree by the Python None
- This would be isomorphic to the Class version with default printing

#### Operations (1)

- We now provide functions to create, inspect and take apart binary trees
- The code with the line numbers is the code for the implementation using namedtuples

```
def mkEmptyBT() -> Tree :
    return EmptyBT()

def mkNodeBT(x : T,t1 : Tree,t2 : Tree) -> Tree :
    return NodeBT(x,t1,t2)

def isEmptyBT(t : Tree) -> bool:
    return t == EmptyBT()
```

- mkEmptyBT, mkNodeBT are constructor functions we could have used the raw named tuples but the discipline is good for you and it makes it easier to refactor in future
- isEmptyBT uses the == operator for identity check (not identity (is))

#### Operations (2)

The code with no line numbers illustrates how the previous implementation using Class Tree can be given the same operations interface

```
def mkEmptyBT() -> Tree :
    return Tree()

def mkNodeBT(x : T,t1 : Tree,t2 : Tree) -> Tree :
    return join(x,t1,t2)

def isEmptyBT(t : Tree) -> bool:
    return is_empty(t)
```

**Binary Tree** Exercises Commentary 6

**Future Work** References

- Operations (5)
  - Here are the operations heightBT() and sizeBT()
  - Note that height of an empty tree is 0

```
59 def heightBT(t : Tree) -> int :
    if isEmptyBT(t):
      return 0
    else:
62
      return (1 + max(heightBT(getLeftBT(t)))
63
                      .heightBT(getRightBT(t))))
64
66 def sizeBT(t : Tree) -> int :
    if isEmptyBT(t) :
68
      return 0
    else:
69
      return (1 + sizeBT(getLeftBT(t))
70
                + sizeBT(getRightBT(t)))
71
```

- The Class Tree implementation of the above operations is exactly the same
- If we make height or size directly part of the data structure this may change

#### Tree Traversals

- Many applications require visiting each node in a binary tree and doing some processing.
- This could be adding quantities to find a total, identifying the number of nodes with a particular property and so on.
- ► There are several common patterns of visiting each node or traversing a tree
  - Depth first where the search tree is deepened as much as possible on each child before visiting the next sibling
  - ► Breadth first where we visit every node on a level before visiting the next level
- ► Each traversal takes a tree and returns a list of items at the nodes of the tree

Commentary 6

Future Work

- 1. If t is an empty tree then return the empty list
- 2. Otherwise do an In Order traversal of the left subtree of t then append a list just containing the data item at the root of t followed by an In Order traversal of the right subtree of t
- Pre-Order traversal of tree t
  - As In-Order but output a list with the item at the root of t before traversing the two subtrees
- Post-Order traversal of tree t
  - As Pre-Order but output a list with the item at the root of t after traversing the two subtrees
- In-Order, Pre-Order and Post-Order traversals are collectively termed Depth First Traversals
- We first provide the usual recursive implementations in a later section we translate the recursive versions into iterative versions

#### Tree Traversals

#### **Breadth First**

- The M269 book section 16.3.5 gives an iterative version of a breadth first traversal but only mentions a recursive version briefly
- We shall start with a recursive version and transform that by stages into the iterative version in the book
- ▶ I find it easier to think of the recursive version first you should observe how people think they think about programming
- First we do some exercises

Activity 4 Breadth First Traversals

- ► A *level order* traversal of a binary tree takes a tree and returns the list of levels
- Each level is the list of items at that level
- Give the list of levels for:
- ► egBSTree
- ► egBSTreeL
- egBSTree1
- egBSTree2
- ▶ egBSTree3

- (1) An empty tree has an empty list of levels (level zero)
- (2) A non-empty tree has the list of the root item followed by combining the two lists of the levels for the two sub-trees
  - We will call the function that combines the two lists of levels longZipMerge() since it is similar to the Python library zip() function

```
def levelOrderBT(t : Tree) -> [[T]] :
428
       if isEmptyBT(t) :
429
         return []
430
       else:
431
432
         x = qetDataBT(t)
433
         left = getLeftBT(t)
         right = getRightBT(t)
434
         return ([[x]] +
435
           longZipMerge(levelOrderBT(left),levelOrderBT(right)))
436

- longZipMerge() is a variant on the Python library function zip()
- zip() iterates over several iterables in parallel, producing tuples with an item from each one.
- longZipMerge() takes two lists and returns a new list with merged pairs of items from each list which is a level order traverse of the subtrees
- ► The two lists do not need to be of the same length any excess is just appended to the merged result so far

```
def longZipMerge(xss : [[T]],yss : [[T]]) -> [[T]] :
438
439
       if xss == []:
         return vss
440
       elif yss == [] :
441
         return xss
442
       else:
443
         return ([xss[0] + yss[0]] + longZipMerge(xss[1:],yss[1:]))
444

Version 01 (g)

- ▶ levelOrderBT01() is not only of the wrong type but produces the wrong order except for a limited number of trees
- The Python type annotations are only checked for syntax but not for correctness
- We get the final breadthBT01() by flattening the list of levels
- This uses a list comprehension as a shorthand for nested loops — see explanation below

```
def flattenLevels(levels : [[T]]) -> [T] :
454
      return ([elem for level in levels for elem in level])
455
```

def breadthBT01(t : Tree) -> [T] : 457 return flattenLevels(levelOrderBT(t)) 458

79/338

- Python List comprehensions (tutorial), List comprehensions (reference) — a neat way of expressing iterations over a list
- Example (a) Square the even numbers between 0 and 9
- Example (b) Generate a list of pairs which satisfy some condition

```
Python3>>> [x ** 2 for x in range(10) if x % 2 == 0]
[0, 4, 16, 36, 64]
Python3>>> [(x,y) for x in range(4)
                   for y in range(4)
                  if \times \% 2 == 0
                      and y \% 3 == 0]
[(0, 0), (0, 3), (2, 0), (2, 3)]
Pvthon3>>>
```

In general

```
[expr for target1 in iterable1 if cond1
      for target2 in iterable2 if cond2 ...
      for targetN in iterableN if condN ]
```

491

492

493

494

495

- Instead of the list comprehension, flattenLevels() could be defined with an accumulating list and nested loops.
- M269 does not mention list comprehensions so you would have to decide whether they are worth mentioning

```
490 def flattenLevelsA(levels : [[T]]) -> [T] :
    accumList = []
    for level in levels :
      for elem in level :
        accumList = accumList + [elem]
    return accumList
```

81/338

- We now have a correct program breadthBT01() but this does lots of (how many?) traversals of the data we may want a more efficient version and hence we transform our program
- Version 02 uses a helper function bfTraverse(vs,ts) which takes a list of item seen, vs, and a list (or queue) of trees to be visited, ts
- As we visit a node, we add its subtree to the queue, ts

```
501 def breadthBT02(t : Tree) -> [T] :
    return bfTraverse([].[t])
504 def bfTraverse(vs : [T],ts : [Tree]) -> [T] :
     if ts == []:
505
506
      return vs
    elif isEmptyBT(ts[0]):
507
      return bfTraverse(vs,ts[1:])
508
    else:
509
510
      return (bfTraverse(vs + [getDataBT(ts[0])],
                   ts[1:] + [getLeftBT(ts[0]),getRightBT(ts[0])]))
511
```

Commentary 6

- Version 02 removed some of the recursion by enqueueing trees to be visited
- This version has the disadvantage that no output until all the nodes are visited, which could mean a long wait or never if the tree is infinite
- Version 03 enables a lazier approach Python could use a Generator expression or augment the code with Yield expressions (both not used in M269) but other languages, such as Haskell use lazy evaluation by default

```
513 def breadthBT03(t : Tree) -> [T] :
    return lbfBT([t])
516def lbfBT(ts : [Tree]) -> [T] :
    if ts == □:
517
518
      return []
519
    elif isEmptyBT(ts[0]):
      return lbfBT(ts[1:])
520
    else:
521
      return ([getDataBT(ts[0])]
522
           + lbfBT(ts[1:] + [getLeftBT(ts[0]),getRightBT(ts[0])]))
523
```

AVL Trees

AVL Trees: Sets Commentary 5

Binary Tree Exercises Commentary 6

Future Work 83/338

Version 04 (a)

- Version 03 has the only recursive call as (almost) the last thing
- So we can implement this with a while loop

```
527 def breadthBT04(t : Tree) -> [T] :
     ts = [t] # Trees to visit
528
             # Values seen
529
     while (ts != []) :
530
       if not (isEmptyBT(ts[0])) :
531
         vs = vs + [getDataBT(ts[0])]
532
         ts = ts[1:] + [getLeftBT(ts[0]),getRightBT(ts[0])]
533
534
       else:
         ts = ts[1:]
535
536
     return vs
```

Answer 5 Breadth First Error

- ► The error is the while condition at line 546
- isEmptyBT(ts) will never return True since ts is a list of trees
- ► The article version of these notes contains an output of the print statements and the error report
- ► The error is reported at line 548 as IndexError: list index out of range
- So the print statements do not show the real error
- ► The Python interpreter does not check the type annotations for correctness, just the syntax
- Remember that Python is a weakly typed language

languages (such as Haskell).

Adobe Connect Commentary 2

This has made it easier to produce correct and fairly simple implementations

**Binary Trees** 

Agenda

This is mainly because the binary tree data structure is itself defined recursively

Iterative Traversals Iterative InOrder

A binary tree is either an empty tree or a node with a data item and two subtrees.

Traversal Iterative PreOrder Traversal Iterative PostOrder Traversal

However the efficiency of this approach will depend on how the chosen programming language is implemented.

Commentary 3 **Binary Search Trees** 

We are using Python and, while Python permits recursion, it does not do some of the optimisations available in other languages, especially pure functional Commentary 4

AVI Trees

AVI. Trees: Sets

Commentary 5 Binary Tree

Exercises Commentary 6

**Future Work** 

References

Hence you may find some Python texts down play the use of recursion

#### Iterative Tree Traversals

#### Recursion Removal

- It is always possible to convert a recursive program into one that just uses iteration with while loops or (possibly) for loops
- We give below examples of the depth first tree traversals translated from their recursive forms to non-recursive.
- Note that this subsection is for illustration only and you would not be expected to be able to reproduce the code or convert other recursive code.

#### Iterative Tree Traversals

inOrder Traversal (5)

#### **Algorithm Description**

- inOrderIterBT2 takes a tree t and returns a list of items at the nodes, depth first from left to right
  - 1. Initialise result to an empty list, and stack, for the stack of trees to visit, to an empty list
  - 2. While stack is not empty or t is not the empty tree
    - 2.1 If t is not empty, append t to stack and assign t to be its left sub tree this is the left recursion
    - 2.2 Otherwise make t the top of the stack (and remove it), append the item at its node to result and make t to be its right sub tree
  - 3. Finally return result

#### **Iterative Tree Traversals**

postOrder Traversal (4) — Algorithm Description

- 1. Initialise result to an empty list.
- If t is empty then return result (not really needed since the loop would take care of this)
- 3. Initialise stack, for the stack of trees to visit, to an empty list
- 4. While stack is not empty or t is not the empty tree
  - 4.1 While t is not the empty tree
    - ► If the right sub tree of t is not empty, push it on to stack
    - Append t to stackAssign t its left sub tree
  - 4.2 Pop a node from stack and set it as t
  - 4.3 If the popped node has a non empty right child and the right child is at the top of stack
    - Remove the right child from the stack
    - Push the current node t on to stack
    - Set t to be t's right child
  - 4.4 Otherwise
    - Append the data at the root of t to result
    - Set t to Empty() marking t as visited, prevents infinite looping (it is t.rightBT)
- 5. Finally return result

#### Iterative Tree Traversals

#### **Concluding Points**

- Recursive versions are easier to get right.
- Iterative versions mimic the stack of recursive function calls.
- Other non-recursive versions use different data structures with pointers to parent nodes. The code is still more complex (and error prone) compared to the recursive versions.

# **Binary Search Trees**

#### Definition

- A binary search tree (BST) is a binary tree with the binary search tree property:
  - 1. The left sub tree contains nodes with keys less than the root node
  - 2. The right sub tree contains nodes with keys greater than the root node
  - The left and right sub trees must also be binary search trees
  - 4. No nodes with duplicate keys
  - 5. An empty tree is a binary search tree
  - 6. Nothing else is a binary search tree
- The data at each node is to contain a key and any values. The operations required for a BST will include:

```
insertBST(), inBST(), isBSTree(),
insertListBST(), buildBST(), deleteBST()
```

## **Binary Search Trees**

#### Motivation

- A perfect binary tree of height h will have  $2^h 1$  nodes
- ► This means that there will be at most  $log_2(n+1)$  steps from the root of the tree to any node in the tree.
- ► This provides the basis for efficient searching if we give an appropriate structure to the tree — a *Binary Search Tree (BST)*
- ► However we have to keep the BST as near to a perfect tree otherwise we lose the advantage

#### Perfect Trees

#### Answer 6 Nodes of Perfect Tree

- There are many ways of showing that a perfect binary tree of height h will have  $2^h - 1$  nodes — here is one way
- Let  $N_h$  be the number of nodes in a perfect tree and  $L_h$ be the number of leaves in the same tree.
- ► Then we have  $L_0 = 0$ ,  $L_1 = 1$ ,  $L_2 = 2$ ,  $L_3 = 4$ ,... and in general  $L_h = 2^{h-1}$ .  $h \ge 1$
- Now  $N_h = L_1 + L_2 + \cdots + L_h = 2^0 + 2^1 + \cdots + 2^{h-1}$
- $\triangleright$  2N<sub>h</sub> = 2<sup>1</sup> + 2<sup>2</sup> + · · · + 2<sup>h-1</sup> + 2<sup>h</sup>
- Subtract the  $N_h$  from  $2N_h$  and we get  $N_h = 2^h 1$
- Notice that  $N_h = 1 + 2 \times N_{h-1}$  when we consider the performance we will use similar recurrence relations

# Inserting a Node

#### Description

- ► The function that takes a item (key and payload) and an existing BST has to return a new binary tree with the item inserted and the new tree must be a BST. We deal with each possible binary tree: an empty tree and a non-empty tree:
- To insert an item into an empty tree, we return a new tree which is a singleton node with the item and two empty sub-trees.
- ► To insert an item, with key k, into a tree which is a node with an item with key p and two sub-trees then we have two possibilities
  - If k is less than p then insert the item in the left sub-tree
  - If k is greater than p then insert the item in the right sub-tree
- We are going to assume duplicate keys are not allowed

Commentary 6

Future Work

Building a Binary Search Tree from a list of items

We could insert a list of items one by one from the list in turn — here is the Python code:

```
595 def insertListBST(xs,t) :
     if xs == [] :
       return t
597
    else:
598
       return insertListBST (xs[1:], insertBST(xs[0],t))
599
```

However, see what happens when we insert various lists

— how compact is the resulting tree?

Notice that tree tKeys2 has height equal to the number of items 11

The structure might as well be a list

In this case the tree structure would not be more efficient than a list for searching.

The height of tKeys3 is 4 which is as compact a tree with the number of items between 8 and 15.

tKeys2 shows inserting a list in even partly sorted order results in the worst case for efficiency.

If a binary search tree is built from insertion of a list of random data then it can be shown that the expected height of the tree is O(log n)

► The proof of this requires knowledge of statistics outside the remit of this course — if interested, a proof is in Cormen et al. (2009, page 300) *Theorem 12.4* and Cormen et al (2022, page 328) *Problem 12-3* 

► Go to Activity

**Building a Compact BST** 

- ➤ To produce as compact a tree as possible, we could we could do the following:
- Sort the list
- Find the middle item in the sorted list
- Construct a binary tree node with the middle item as the data
- The left and right sub-trees should be formed by recursively building binary trees from the front and back parts of the sorted list
- Below is an implementation in Python

**Binary Trees** 

- Deleting an item from a binary search tree involves more choices than insertion
- Initial insight
  - Find the node with the item (key) by following left or right sub trees
  - Delete the item by joining the two sub trees of the node
  - ► If the item is not in the tree, just return mkEmptyBT()
- The tricky bit is deciding how to join the two sub trees while keeping the binary search tree property and keeping the tree compact (otherwise we lose the advantage of a binary search tree).
- ► The following presents three alternatives which each use some information about binary search trees — each version is correct but the later versions produce a more compact tree.
- Below is the initial insight implemented in Python:

### ioinBST

#### Version 2

joinBST1 results in a near linear structure and is not as compact as it could be.

- The first definition made no use of our knowledge of binary search trees.
- ▶ We know that:

maxKey leftT < minKey rightT</pre>

since they were subtrees of the original Binary Search tree, egBSTreeL

- In particular we therefore know that the root of the left subtree is less than any item in the right subtree.
- So we attach the left subtree under the smallest element in the right sub tree.

**Future Work** 

# Deleting an Item from a BST

Answer 11 joinBST Version 2

Hence the final value is

```
NodeBT('F',
   NodeBT('E',
      NodeBT('B',
      NodeBT('A', EmptyBT(), EmptyBT()),
      NodeBT('C', EmptyBT(), EmptyBT())),
   EmptyBT()),
NodeBT('G', EmptyBT(), EmptyBT()))
```

- Doing a step by step evaluation of recursive function calls should help you get a better feel for recursive thinking.
- ▶ We can do better than this see the following.

#### **Final Version**

We can make better use of our knowledge of Binary Search trees

▶ We know that:

maxKey leftT < root key < minKey rightT</pre>

- Hence we can promote the minimum item in the right subtree to be the new root and delete it from its original position.
- ▶ **Note** we could equally well promote the maximum item in the left subtree to be the new root (and delete it from its original position).

Commentary 6

Future Work

Here is Python code for the above diagram:

```
696 def joinBST(leftT, rightT):
     if isEmptyBT(rightT):
       return leftT
698
     else:
699
       (y,t) = splitBST(rightT)
700
       return mkNodeBT(v. leftT. t)
701
```

- splitBST will take the right subtree and return a pair of minimum item and the subtree with that item removed.
- This preserves much of the compact nature of the binary search tree.

- We still have choices in defining splitBST
- ► We could define splitBST by finding the minimum item and then deleting that from the subtree.

```
706 def splitBST1(t):
707
     if isEmptyBT(t):
       raise RuntimeError("splitBST1 applied to EmptyBT()")
708
     elif isEmptyBT(getLeftBT(t)):
709
       return (getDataBT(t), getRightBT(t))
710
     else:
711
       y = minItemBST(getLeftBT(t))
712
       return (y, mkNodeBT(getDataBT(t),
713
714
                          deleteBST(y, getLeftBT(t)),
                          getRightBT(t)))
715
717 def minItemBST(t):
718
    if isEmptyBT(t):
       raise RuntimeError("minItemBST applied to EmptyBT()")
719
     elif isEmptyBT(getLeftBT(t)):
720
721
       return (getDataBT(t))
722
     else:
       return (minItemBST(getLeftBT(t)))

## splitBST

#### **Final Version**

- We can do better than splitBST1
- It is possible to define splitBST using only one traversal of the tree

```
727 def splitBST(t):
     if isEmptyBT(t):
728
       raise RuntimeError("splitBST_applied_to_EmptyBT()")
729
     else:
730
       x = getDataBT(t)
731
       t1 = qetLeftBT(t)
732
       t2 = getRightBT(t)
733
734
       if isEmptyBT(t1):
735
         return (x.t2)
       else:
736
         (v.t3) = splitBST(t1)
737
         return (v. mkNodeBT(x. t3. t2))
738
```

Answer 12 Split Trace

► Evaluation of splitBST(egBSTreeLR)

### Step 1

getLeftBT(egBSTreeLR) is not empty so the else
clause at line 736 is executed

## Step 2

A recursive call is made to splitBST with argument getLeftBT(egBSTreeLR)

getLeftBT(getLeftBT(egBSTreeLR)) is empty so the
if at line 734 returns

('E',getRightBT(getLeftBT(egBSTreeLR))) which
is ('E',EmptyBT())

#### Performance

- ► As we noted earlier, on average the height of a binary search tree is  $O(\log n)$  where n is the number of nodes in the tree.
- ► However in the worst case the height is *O*(*n*) and this will affect the performance of searches.
- However it is possible to construct variants of binary search trees which have O(log n) performance in both average and worst cases
- In the next section we will consider one approach.

Height Balanced Trees (AVL Trees)

## 4 Height Balanced Trees

- Binary search trees with the height balanced property
- Also called AVL trees
- Inserting a node
- AVL transformations
- Local changes preserve global AVL property
- Deletion
- AVL trees application: representing sets (advanced topic)
- Note: Haskell uses the same ideas but with size balanced trees
- Python uses something like dictionaries to implement sets using hashtables

# Height Balanced Trees

#### Introduction

- Binary search trees have the problem that in the worst case the complexity of a search could be O(n) and maintaining a complete tree during insertions and deletions involves too much restructuring.
- ► A solution is to keep the tree *balanced* so that access time is still *O*(log *n*) in both the average and worst cases.
- The essential approach is to have some local transformations involving only a few nodes to keep the tree height balanced.
- ► We shall consider one approach called *AVL Trees*, named after the Russian inventors G M Adelson-Velskii and F M I andis
- AVL Trees are Binary Search Trees with the property that for every subtree the heights of the trees differs by at most 1 (the balance factor).
- AVL trees require an extra couple of functions to maintain the AVL property on each insertion or deletion.

### Data Type

- As with the Binary Search Tree, we shall use a union of named tuples to represent the data type for an AVL Tree.
- Note that we store the height of a tree in the node
- This is essential to avoid lots of tree traversals to re-calculate balance factors

**Binary Trees** 

Phil Molvneux

#### Health Warning

- Some texts define the height of a singleton node to be zero — just subtract one from the height as defined here.
- Some texts do not use empty trees so where these notes might say a singleton nodes has an element and two empty subtrees, some texts might say a singleton node has no subtrees
- Some texts define the height of a subtree differently to the height of a tree or define a subtree differently to here.
- Some texts define the balance factor as the absolute value or the height of the right sub tree minus the height of the left sub tree
- In all cases be aware that you have choices in the exact definition of some terms but the ideas will be the same.

# Heights and Balance Factors

Activity 16 Add Item LL

- Add the item with key 7 to the tree, egNSTree04, and recalculate the heights and balance factors
- Identify the lowest node in the tree which is out of balance.

## **AVL Tree Transformations**

### Sample Tree

Since the subtree of egBSTree04b = insertBST(7, egBSTree04) at node with key 15 is the part of the tree out of balance we shall focus on that

```
NodeABT(4, 15,
  NodeABT(3, 11,
    NodeABT(2, 5,
    EmptyABT(),
    NodeABT(1, 7, EmptyABT(), EmptyABT())),
  NodeABT(1, 13, EmptyABT(), EmptyABT())),
  NodeABT(1, 18, EmptyABT(), EmptyABT()))

## **AVL Tree Transformations**

#### **Example Transformation**

- We can make this tree balanced by
- Make the subtree with root 15 the right child of 11
- Make the subtree with root 13 the left child of 15
- Leave the subtree with root 5 as the left child of 11
- Make the new subtree with root 11 the child of wherever the original subtree with root 15 was (the left child of 21)
- This results in the following tree.

```
NodeABT(3, 11,
   NodeABT(2, 5,
   EmptyABT(),
   NodeABT(1, 7, EmptyABT(), EmptyABT())),
NodeABT(2, 15,
   NodeABT(1, 13, EmptyABT(), EmptyABT()),
   NodeABT(1, 18, EmptyABT(), EmptyABT())))
```

### Python

- ► This transformation is an instance of what is called a *right rotation*
- Here is Python code that implements it.

```
843 def rotr(t):
     k = getDataABT(t)
     kL = getDataABT(getLeftABT(t))
845
     leftLeftT = getLeftABT(getLeftABT(t))
846
     leftRightT = getRightABT(getLeftABT(t))
847
     rightT = getRightABT(t)
848
     return (mkNodeABT(kL,
849
850
                         leftLeftT,
                         mkNodeABT(k, leftRightT, rightT)))
851

#### Answer 18 Rebalance RR

- We can make this tree balanced by:
- Make the subtree with root 41 the left child of 92
- Make the subtree with root 55 the right child of 41
- Leave the subtree with root 97 as the right child of 92
- Make the new subtree with root 92 the child of wherever the original subtree with root 41 was (the right child of 34)

```
NodeABT(3, 92,
NodeABT(2, 41,
NodeABT(1, 36, EmptyABT(), EmptyABT()),
NodeABT(1, 55, EmptyABT(), EmptyABT())),
NodeABT(2, 97,
NodeABT(1, 96, EmptyABT(), EmptyABT()),
EmptyABT()))
```

Left Rotation — Python

- ► The transformation (given in the answer) is an instance of what is called a *left rotation*
- Here is the Python code that implements it.

```
853 def rotl(t):
     k = getDataABT(t)
     kR = getDataABT(getRightABT(t))
855
     rightLeftT = getLeftABT(getRightABT(t))
856
     rightRightT = getRightABT(getRightABT(t))
857
     leftT = t.leftART
858
     return (mkNodeABT(kR,
859
860
                         mkNodeABT(k, leftT, rightLeftT),
                         riahtRiahtT))
861
```

► This is a mirror image of the *right rotation* as you can see from the two diagrams describing it below.

#### Insight

- The functions for insertion and deletion of an item in an AVL tree will be the same as a Binary Search tree except
- When we construct a new tree we must maintain the AVL property via a function makeAVLTree (line 865 on slide 210) not just makeABTree (line 764 on slide 167). (some texts call this rebalancing or something similar)
- What we know is that the original tree must be a properly formed AVL tree and that the insertion or deletion of one item can alter the height of any subtree by at most 1.
- Hence we can implement makeAVLTree(x, leftT, rightT) assuming that leftT and rightT are both AVL trees whose heights differ by at most 2.
- We proceed by analysing each possible case and provide a manipulation of the tree for each case. Consider the diagram below:

Cases Diagram

- Our right and left rotation functions, rotr and rotl have dealt with the cases where the subsubtrees LL and RR had increased by one caused the balance to go outside the permitted range.
- We now have to investigate cases where the subsubtrees LR or RL become heavy.
- ► Below is an example, egBSTree05

#### LR Heavy

- ► This has just switched the balance factor of the root of the tree from 2 to -2 so we have to do something else.
- ► The Eureka step is realising that we can break up the problematic subtree under node 18 by doing a left rotation around node 15 — this produces the following tree.

#### The makeAVLTree Function

- ► The makeAVLTree takes an item, x, two subtrees, leftT, rightT and returns a new augmented binary tree
- ▶ It would be the same as makeABTree except it has to do the appropriate transformation if the new tree would be out of balance.
- We will only ever use makeAVLTree when inserting or deleting an item in a valid AVL tree
- So we know from our insight above that the heights of leftT and rightT can differ by at most 2 after insertion/deletion
- Hence we consider each case in turn using the transformations we have developed above.

#### Conclusions

- This section has been quite long but most of the space has been occupied with diagrams
- Some implementations can look quite tricky since they may be trying to avoid recursion or manipulate the data structures
- We will discuss efficiency and recursion removal in a later section.
- Here are diagrams of the two rotate functions to emphasise that they are really quite simple.

#### Comparison with Storing Balance Factors

- Some texts implement AVL Trees by storing balance factors at the nodes rather than the heights (Miller and Ranum, 2011, Section 6.8.2, page 290)
- ► The Miller and Ranum explanation of updating the balance factors after a right or left rotation refer to diagrams similar to rotate right on slide 212 and rotate left on slide 213
- This note translates the Miller & Ranum notation to the notation used in these diagrams
- Both approaches have performance O(log n) but have differences in detail

Right Rotation (1)

- ► New and old balance factors of node k
- Using pseudo-code:

```
newBal(k) = height(tLR) - height(tR)
oldBal(k) = oldHeight(kL) - height(tR)
          = (1 + max(height(tLL), height(tLR)))
            - height(tR)
newBal(k) - oldBal(k)
  = (height(tLR) - height(tR))
    - ((1 + max(height(tLL), height(tLR)))
       - height(tR))
  = height(tLR)
    - 1 - max(height(tLL), height(tLR))
  = height(tLR)
    - 1 + min(-height(tLL), -height(tLR))
  = min(height(tLR) - height(tLL)
       , height(tLR) - height(tLR)) - 1
  = \min(-oldBal(kL), 0) - 1
    since -max(a, b) = min(-a, -b)
           min(a,b) + c = min(a+c, b+c)
```

Right Rotation (3)

Right rotation: New and old balance factors of nodes k and kR

```
newBal(k)
  = oldBal(k) + min(-oldBal(kL), 0) - 1
newBal(kL)
  = oldBal(kL) + min(0, newBal(k)) - 1
```

This fits with the right rotation diagrams annotated with heights and balance factors on slide 181,

```
oldBal(k)
oldBal(kL) = +1
newBal(k) = 0 = +2 + min(-1, 0) - 1
newBal(kL) = 0 = +1 + min(0, 0) - 1
```

# Comparison with Storing Balance Factors

Left Rotation (1)

- ► New and old balance factors of node k
- Using pseudo-code:

```
newBal(k) = height(tL) - height(tRL)
oldBal(k) = height(tL) - oldHeight(kR)
          = height(tL)
            - (1 + max(height(tRL), height(tRR)))
newBal(k) - oldBal(k)
  = (height(tL) - height(tRL))
    - (height(tL)
       - (1 + max(height(tRL), height(tRR))))
  = 1 + max(height(tRL), height(tRR)) - height(tRL)
  = 1 + max(height(tRL) - height(tRL)
           , height(tRR) - height(tRL))
  = 1 + \max(0, -oldBal(kR))
  = 1 - \min(0. \text{ oldBal(kR)})
    since max(-a, -b) = -min(a,b)
          \max(a,b) - c = \max(a-c, b-c)
```

#### Insertion and Deletion

The insertion and deletion functions are the same as for Binary Search Trees except we have to use makeAVLTree to make a tree unless we really know that the AVL property will be preserved.

```
881 def insertAVLT(x,t):
     if isEmptyABT(t):
882
       return mkNodeABT(x, mkEmptyABT(), mkEmptyABT())
883
    else:
884
885
       v = qetDataABT(t)
       leftT = getLeftABT(t)
886
       rightT = getRightABT(t)
887
       if x < y:
888
         return makeAVLTree(y, insertAVLT(x, leftT), rightT)
889
       elif x > y:
890
         return makeAVLTree(y, leftT, insertAVLT(x, rightT))
891
       else:
892
893
         return t
```

```
895 def insertListAVLT(xs,t):
896   if xs == []:
897   return t
898   else:
899   return insertListAVLT(xs[1:], (insertAVLT(xs[0],t)))

#### Activity 22 Insert Lists and Delete Items

- Draw the AVL Trees resulting from inserting the following lists of items into an empty tree one by one in order given — do the insertions by hand following the AVL insertion algorithm — you can use the Python code to check your answers
  - 1. [1,2,3,4,5,6,7,8,9,10]
  - 2. [10,9,8,7,6,5,4,3,2,1]
  - 3. [68,88,61,89,94,50,4,76,66,82,99]
- For each of the previous trees, show the result when the fourth item inserted is deleted
- The insertAVLT function is defined at line 881, slide 221 (Python), the deleteAVLT function is defined at line 901, slide 222 (Python),
- insertListAVLT is defined at line 895, slide 221 (Python),

Answer 24 Delete with Rebalance (4)

- ► Key k is 55
- ► Key kR is 68
- ► Key kRL is 59
- ► Subtree tL is rooted at 29
- ► Subtree tRL is rooted at 59
- ► Subtree RR is rooted at 86
- Subtree tRLL is an empty tree
- Subtree tRLR is rooted at 65
- ► The given tree is an instance of RL heavy
- This requires a double rotation to rebalance

Future Work

- For a tree with *n* items we shall show that the maximum number of steps to insert, delete or retrieve an item is  $O(\log n)$
- Finding the maximum height of a tree with n items is equivalent to finding the minimum number of items, T<sub>h</sub> in a tree of height h
- For h = 0 we have an empty tree so  $T_0 = 0$
- For  $T_1$  we have a singleton item so  $T_1 = 1$
- ▶ In general for  $h \ge 2$  we have  $T_h = 1 + T_{h-1} + T_{h-2}$  since the tree must be balanced and each subtree must have a minimum number of items

**Binary Trees** 

Commentary 6

- ► The sequence *T<sub>h</sub>* looks very similar to the Fibonacci sequence
- $F_0 = 0, F_1 = 1$
- $F_k = F_{k-1} + F_{k-2}, k \ge 2$
- ► The Fibonacci sequence appeared in a work by Leonardo Fibonacci Pisano, who also popularized the Hindu-Arabic numeral system via his 1202 book *Liber Abaci (Book of Calculations)*.
- The sequence also appeared in Indian mathematics much earlier.
- ► The Fibonacci numbers have lots of interesting properties and turn up in many places in nature
- In our case we have  $T_h = F_{h+2} 1$

#### Performance (2a)

- ▶ Deriving  $T_h = F_{h+2} 1$
- ► Let  $R_h = T_h T_{h-1} = 1 + T_{h-2}$
- ► Then  $R_{h+2} = 1 + T_h = 1 + 1 + T_{h-1} + T_{h-2} = R_{d+1} + R_d$
- $R_2 = 1 + T_0 = 1 + 0 = 1 = F_2$  and  $R_3 = 1 + T_1 = 1 + 1 = 2 = F_3$
- ► Hence  $R_h = F_h$ ,  $\forall h \ge 2$
- ► Hence  $T_h = F_{h+2} 1$ ,  $\forall h \ge 0$

Commentary 6

#### Performance (2b)

- Miller & Ranum approach
- Level number of edges from root to node
- ► **Height** maximum level of any node in the tree this is one less than my definition
- N<sub>h</sub> is the minimum number of nodes in an AVL tree of height h
- N<sub>0</sub> = 1 since tree of one node has no edges  $N_1 = 2$
- $N_h = 1 + N_{h-1} + N_{h-2}, \ h \ge 2$
- Let  $S_h = N_h N_{h-1} = 1 + N_{h-2}$
- ► Then  $S_{h+2} = 1 + N_h = 1 + 1 + N_{h-1} + N_{h-2} = S_{d+1} + S_d$
- S<sub>2</sub> = 1 + N<sub>0</sub> = 1 + 1 = 2 =  $F_3$  and S<sub>3</sub> = 1 + N<sub>1</sub> = 1 + 2 = 3 =  $F_4$
- ► Hence  $S_h = F_{h+1}$ ,  $\forall h \ge 2$
- ► Hence  $N_h = F_{h+3} 1$ ,  $\forall h \ge 0$

#### Performance (2c)

- P(h):  $T_h = F_{h+2} 1$  proof by induction
- ▶ **Basis** *P*(0), *P*(1)
- $T_0 = 1$  and  $F_2 1 = 1 1 = 0$
- $T_1 = 1$  and  $F_3 1 = 2 1 = 1$
- ▶ Inductive step  $\forall k P(k) \Rightarrow P(k+1)$

$$T_k = 1 + T_{k-1} + T_{k-2}$$

$$= 1 + (F_{k+1} - 1) + (F_k - 1)$$

$$= F_{k+2} - 1$$

► Hence  $T_h = F_{h+2} - 1$ ,  $\forall h \ge 0$

Commentary 6

Future Work

- There is a closed-form solution for the Fibonacci sequence known as the Euler-Binet Formula (see also A formula for Fib(n))
- $F_k = \frac{\phi^k (1 \phi)^k}{\sqrt{5}}$
- $\blacktriangleright$   $\phi$  is the Golden mean
- $\phi = \frac{1}{\phi 1} = \frac{1 + \sqrt{5}}{2} \approx 1.61803...$
- ► Hence  $T_h = \frac{\phi^{h+2} (1-\phi)^{h+2}}{\sqrt{c}} 1$
- ▶ Since  $(1 \phi)$  < 1 then for large h we have
- $T_h = n \approx \frac{\phi^{h+2}}{\sqrt{5}} 1 \rightarrow \log(\sqrt{5}(n+1)) \approx (h+2)\log\phi$
- Hence in the worst case, the height of a AVL tree is  $O(\log n)$

## Fibonacci Euler-Binet Formula

Proof (1a)

- Proof of the Euler-Binet Formula is not required for M269 but here is a brief summary
- Proof by Induction

► Let 
$$P(n) = F_n = \frac{\phi^n - (1 - \phi)^n}{\sqrt{5}}$$

- Basis for Induction
- $\triangleright$  P(0) is true since

$$\frac{\phi^0 - (1 - \phi)^0}{\sqrt{5}} = \frac{1 - 1}{\sqrt{5}} = 0 == F_0$$

 $\triangleright$  P(1) is true since

$$\frac{\phi^1-(1-\phi)^1}{\sqrt{5}}=\frac{\left(\frac{1+\sqrt{5}}{2}\right)-\left(1-\left(\frac{1+\sqrt{5}}{2}\right)\right)}{\sqrt{5}}$$

$$ightharpoonup = 1 == F_1$$

## Fibonacci Euler-Binet Formula

Proof (1b)

### Induction Hypothesis Step

► Show 
$$P(j): 0 \le j \le k+1 \Rightarrow P(k+2)$$

$$\phi^{k+2} - (1-\phi)^{k+2} = \phi^2 \phi^k - (1-\phi)^2 (1-\phi)^k$$
 and

$$\phi^2 = \left(\frac{1+\sqrt{5}}{2}\right)^2 = \frac{1}{4}(1+2\sqrt{5}+5) = 1+\phi$$

$$(1 - \phi)^2 = \left(\frac{1 - \sqrt{5}}{2}\right)^2 = 1 + (1 - \phi) \text{ hence}$$

$$= (\phi^k - (1 - \phi)^k) + (\phi^{k+1} - (1 - \phi)^{k+1})$$

$$= \sqrt{5}(F_k + F_{k+1})$$
 by inductive hypothesis

• = 
$$\sqrt{5}F_{k+2}$$
 by Fibonacci definition

► Hence 
$$\forall n \in \mathbb{N} : F_n = \frac{\phi^n - (1 - \phi)^n}{\sqrt{5}}$$

## Fibonacci Euler-Binet Formula

Proof (2a)

- The above proof confirms the formula but here is a derivation
- ▶ Define T(x, y) = (y, x + y)
- ► Then  $T^n(0, 1) = (F_n, F_{n+1})$  (proof by induction)
- Now find  $\lambda_1, \lambda_2$  and  $(x_1, y_1), (x_2, y_2)$ so  $T(x_1, y_1) = \lambda_1(x_1, y_1)$  and  $T(x_2, y_2) = \lambda_2(x_2, y_2)$ and  $(0, 1) = p_1(x_1, y_1) + p_2(x_2, y_2)$
- $T(x, y) = (y, x + y) = \lambda(x, y)$ 
  - $\rightarrow x + y = \lambda x$  and  $x = \lambda y \rightarrow \lambda^2 \lambda 1 = 0$
  - $\rightarrow \lambda_1 = \phi$  and  $\lambda_2 = 1 \phi$

and  $T(1, \phi) = (\phi, 1 + \phi) = \phi(1, \phi)$ 

$$T(1, 1 - \phi) = (1 - \phi, 1 + (1 - \phi)) = (1 - \phi)(1, 1 - \phi)$$

## Fibonacci Fuler-Binet Formula

Proof (2b)

• 
$$(0, 1) = \frac{1}{\sqrt{5}}(1, \phi) - \frac{1}{\sqrt{5}}(1, 1 - \phi)$$
 confirm by inspection

$$(F_n, F_{n+1}) = T^n(0, 1)$$

$$= \frac{1}{\sqrt{5}} T^n(1, \phi) - \frac{1}{\sqrt{5}} T^n(1, 1 - \phi)$$

$$= \frac{1}{\sqrt{5}} \phi^{n}(1, \phi) - \frac{1}{\sqrt{5}} (1 - \phi)^{n}(1, 1 - \phi)$$

$$= \frac{1}{\sqrt{5}} \phi^{n}(1, \phi) - \frac{1}{\sqrt{5}} (1 - \phi)^{n}(1, 1 - \phi)$$

$$= \frac{1}{\sqrt{5}} (\phi^n, \phi^{n+1}) - \frac{1}{\sqrt{5}} ((1 - \phi)^n, (1 - \phi)^{n+1})$$

$$\blacktriangleright \text{ Hence } F_n = \frac{\phi^n - (1 - \phi)^n}{\sqrt{5}}$$

## **AVL Tree Application**

Sets

- Ordered sets and ordered maps are important data types in programming
- Some programming languages have them as builtin types (Python) or supply them as standard libraries (C++, C#, Java, Scala, Haskell, ML)
- This section describes an example implementation based on Blelloch et al (2016) Just Join for Parallel Ordered Sets and Adams (1993) Functional Pearls Efficient sets — a balancing act
- Note that this example also shows the use of recursive thinking in practice

# **AVL Tree Application**

#### Documentation

- ► In Python the documentation for Sets is at Set Types and for Dictionaries (Maps) at Mapping Types — dict
- ► The Python implementation can be found at the Python Developer's Guide and the source code for Sets is at setobject.c — the implementation is in C using hash tables — see How is set() implemented?
- ► In Haskell the documentation and implementation of Sets is at Containers: Data.Set and for Maps at Containers: Data.Map.Strict — both of these are from the package containers: Assorted concrete container types
- ► The Haskell implementation uses size balanced trees this is similar to AVL balanced trees
- For an introduction see containers Introduction and Tutorial
- For an overview of Sets see Containers: Sets

Set Representation — Split, Join (1)

- The representation of sets uses the ABTree data type but with generalised versions of the split and join functions
- While implementing sets in AVL trees is not directly part of M269, it gives good examples of recursive thinking in an important application
- Note that the data item is used as the key for a node in the tree — in practice there would be separate key and data

#### Activity 26 joinLeftAVLS Bug

- A previous version of joinLeftAVLS had a bug (beware copy/paste) — see below
- ► What would happen if the elements of [10,9,8,7,6] were given as input?

```
def joinLeftAVLS(k: T, tL: ABTree, tR: ABTree) -> ABTree :
    (tRL, kR, tRR) = exposeABT(tR)
    if getHeightABT(tRL) <= getHeightABT(tL) + 1 :
        t1 = mkNodeABT(k,tL,tRL)
        if getHeightABT(t1) <= getHeightABT(tRR) + 1 :
            return mkNodeABT(kR,t1,tRR)
        else :
        return rotr(mkNodeABT(kR,(rotl(t1)),tRR))
else :
        t2 = joinRightAVLS(k,tL,tRL)
        t3 = mkNodeABT(kR,t2,tRR)
        if getHeightABT(t2) <= getHeightABT(tRR) + 1 :
        return t3
        else :
        return rotr(t3)</pre>

 Of course, someone from the pure functional programming world would define a higher order function to capture the recursion pattern with setFoldr() (this is not part of M269)

```
184 def setFoldr(f.z.t):
    def qo(y,t):
185
       if isEmptvABT(t) :
186
187
         return y
188
       else:
         (tL,x,tR) = exposeABT(t)
189
         return (go(f(x,(go(y,tR))),tL))
190
    return qo(z.t)
191
193 def setToAscListA(t) :
194
    def cons(x,xs) :
       return ([x] + xs)
195
    return setFoldr(cons,[],t)
196
```

Answer 29 Subset

```
165 def subsetAVLS(t1: ABTree.t2: ABTree) -> bool :
          isEmptyABT(t1) :
166
       return True
167
    elif isEmptvABT(t2) :
168
       return False
169
    else:
170
171
       (t1L. k1. t1R) = exposeABT(t1)
172
       (t2L, found, t2R) = splitAVLS(k1,t2)
       return (found
173
               and subsetAVLS(t1L,t2L)
174
               and subsetAVLS(t1R,t2R))
175
```

- ► How does this work?
- ► The recursive case at line 170 checks that the key at the root of t1 is in t2 and recursively checks the sub-trees
- splitAVLS() ensures that the subtrees are the correct ones to be checked

### Sets, Maps

#### **Implementation Points**

- The only tree specific functions are joinAVLS, joinRightAVLS and joinLeftAVLS — AVL trees could be changed to size balanced or Red-Black trees with little to be changed
- The various sets operations use splitAVLS and joinAVLS or join2AVLS to avoid more complex algorithms — some implementations may inline the functions for efficiency
- ► The diagrams for joinRightAVLS are essential for the understanding of the base and recursive cases
- The unionAVLS, intersectAVLS and differenceAVLS functions are very similar in their usage of split and join

### Sets, Maps

**Implementation Points** 

- ► From O'Sullivan *Real World Haskell (2008)* see Data Structures
- ▶ Maps give us the same capabilities as hash tables do in other languages. Internally, a map is implemented as a balanced binary tree. Compared to a hash table, this is a much more efficient representation in a language with immutable data. This is the most visible example of how deeply pure functional programming affects how we write code: we choose data structures and algorithms that we can express cleanly and that perform efficiently, but our choices for specific tasks are often different [from] their counterparts in imperative languages.
- ► See Curious about the HashTable performance issues

### **Generating Binary Trees**

#### Exercises

- ► The aim is to generate the shapes of all possible trees given a number of nodes
- First sketch a few trees to spot any pattern
- Write down a recurrence relation for the number of binary tree shapes with n nodes based on the number of tree shapes for less than n nodes
- Write a function genBTs (x,n) given a value x and an integer n generates the Python representation of all shapes of binary trees with n nodes with x at each node

Generating Binary Trees
Catalan Numbers

Commentary 6

Future Work

- Let  $C_n$  be the number of binary tree shapes with nnodes then from the above diagrams we have:
- $C_0 = 1$
- $C_1 = 1$
- $C_2 = 2$
- $C_3 = 5$
- Eureka insight for a tree with n nodes if the left subtree has i nodes then the right subtree must have n-i-1nodes and i can range over 0 to n-1
- ▶ The left and right subtrees must have  $C_i$  and  $C_{n-i-1}$ different possible shapes
- ▶ and there are n possible values for i from 0 to n 1
- $\blacktriangleright \text{ Hence } C_n = \sum_{i=1}^{n} C_i C_{n-i-1}$

Future Work

- ► The simple recursive definition of genBTs follows from the recurrence relation directly
- Uses Python List Comprehensions see below
- This repeats the calculation of subtrees
- ► This is similar to the definition in Math.Combinat.Trees.Binary which is based on Knuth (2011, section 7.2.1.6), Knuth (1997, section 2.3.4.4)

```
239 def genABTs(x: T,n: int) -> [ABTree] :
    if n == 0:
240
      return [mkEmptvABT()]
241
    elif n == 1 :
242
      return [mkNodeABT(x,mkEmptyABT(),mkEmptyABT())]
243
    else:
244
      ts = ([mkNodeABT(x,leftT,rightT)
245
              for (nu,nv) in splitsInt(n)
246
              for leftT in genABTs(x,nu)
247
              for rightT
                         in genABTs(x,nv)])
248
249
      return ts
251 def splitsInt(n: int) -> [(int,int)] :
    prns = [(i, n - i - 1) for i in range(n)]
252
    return prns
253

#### Catalan Numbers

#### **Efficient Calculation**

- As with many other problems, it may be easier to find a recursive relation or recurrence for a problem and harder to find an efficient calculation.
- For the Catalan numbers it is possible to find a closed (non-recursive) expression for the Catalan numbers
- Below is a derivation of a closed expression this is not part of M269 and is included for interest — the derivation uses a bit more Maths than the rest of these notes but it is explained as we progress
- This derivation is from Spivey (2019, page 208) The Art of Proving Binomial Identities and Wilf (1994, page 44) generatingfunctionology

- $C_0 = 1$
- ▶ Define c(x) to be the generating function of the infinite sequence of the Catalan numbers

$$c(x) = \sum_{n=0}^{\infty} C_n x^n$$

Hence we can multiply both sides of the recurrence by x<sup>n</sup> and sum

$$\sum_{n=0}^{\infty} C_{n+1} x^n = \sum_{n=0}^{\infty} \left( \sum_{k=0}^{n} C_k C_{n-k} \right) x^n$$

### Catalan Numbers

Catalan Recurrence (2)

$$\sum_{n=0}^{\infty} C_{n+1} x^n = \sum_{n=0}^{\infty} \left( \sum_{k=0}^{n} C_k C_{n-k} \right) x^n$$

$$\frac{1}{x} \sum_{n=0}^{\infty} C_{n+1} x^{n+1} = (c(x))^2$$
 by Cauchy product

$$\frac{1}{x}(c(x)-1)=(c(x))^2$$

$$x(c(x))^2 - c(x) + 1 = 0$$

$$c(x) = \frac{1 \pm \sqrt{1 - 4x}}{2x}$$

• We know 
$$c(0) = C_0 = 1$$

**Binary Trees**

Catalan Numbers Cauchy Product Catalan Recurrence Sample Catalan

Numbers Commentary 6

**Future Work** References

$$c(x) = \frac{1 \pm \sqrt{1 - 4x}}{2x}$$

- We know  $c(0) = C_0 = 1$
- Applying L'Hôpital's rule

$$\lim_{x\to c}\frac{f(x)}{g(x)}=\lim_{x\to c}\frac{f'(x)}{g'(x)}$$

$$\lim_{x \to 0^+} \frac{1 - \sqrt{1 - 4x}}{2x} = \lim_{x \to 0^+} \frac{2(1 - 4x)^{-\frac{1}{2}}}{2} = 1$$

► Hence 
$$c(x) = \frac{1 - \sqrt{1 - 4x}}{2x}$$

► We now use the generalised Binomial theorem to expand this expression

► The generalised Binomial theorem has

If |x| > |y| and r is any complex number then

$$(x+y)^r = \sum_{k=0}^{\infty} \binom{r}{k} x^{r-k} y^k$$

where 
$$\binom{r}{k} = \frac{r(r-1)\cdots(r-k+1)}{k!}$$

$$c(x) = \frac{1}{2x}(1 - \sqrt{1 - 4x}) = \frac{1}{2x} \left( 1 - \sum_{n=0}^{\infty} {1/2 \choose n} (-4x)^n \right)$$

▶ The coefficient of  $x^n$  expands to

$$\frac{\frac{1}{2}(\frac{1}{2}-1)\cdots(\frac{1}{2}-n+1)}{n!}(-4)^{n}$$

$$=\frac{1(1-2)\cdots(1-2n+2)}{n!}(-1)^{n}2^{n}$$
